Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of technical committees is to prepare International Standards. Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

ISO 19156 was prepared by Technical Committee ISO/TC 211, *Geographic Information/Geomatics*, Subcommittee SC , .

This second/third/... edition cancels and replaces the first/second/... edition (), [clause(s) / subclause(s) / table(s) / figure(s) / annex(es)] of which [has / have] been technically revised.

Introduction

This International Standard arises from work originally undertaken through the Open Geospatial Consortium's Sensor Web Enablement (SWE) activity. SWE is concerned with establishing interfaces and protocols that will enable a "Sensor Web" through which applications and services will be able to access sensors of all types, and observations generated by them, over the Web. SWE has defined, prototyped and tested several components needed for a Sensor Web, namely:

- Sensor Model Language (SensorML).
- Transducer Markup Language (TML)
- Observations & Measurements (O&M)
- Sensor Observation Service (SOS).
- Sensor Planning Service (SPS).
- Sensor Alert Service (SAS).

This International Standard specifies the Observations and Measurements schema, including a schema for Sampling features.

The content presented here has been derived from an earlier version published by Open Geospatial Consortium as OGC 07-022r1 and 07-002r3.

Geographic Information — Observations and measurements

1 Scope

This International Standard defines a conceptual schema for observations, and for features involved in sampling when making observations. These provide models for the exchange of information describing observation acts and their results, both within and between different scientific and technical communities.

Observations commonly involve sampling of an ultimate feature of interest. This standard defines a common set of sampling feature types classified primarily by topological dimension, as well as samples for ex-situ observations. The schema includes relationships between sampling features (sub-sampling, derived samples).

This International Standard concerns only externally visible interfaces and places no restriction on the underlying implementations other than what is needed to satisfy the interface specifications in the actual situation.

2 Conformance

2.1 Overview

Clauses 6 to 10 of this International Standard use the Unified Modeling Language (UML) to present conceptual schemas for describing Observations. These schemas define conceptual classes that (i) may be considered to comprise a cross-domain application schema, or (ii) may be used in application schemas, profiles and implementation specifications.

This flexibility is controlled by a set of UML types that can be implemented in a variety of manners. Use of alternative names that are more familiar in a particular application is acceptable, provided that there is a one-to-one mapping to classes and properties in this standard.

The UML model in this International Standard defines conceptual classes; various software systems define implementation classes or data structures. All of these reference the same information content. There is no difficulty in allowing the use of the same name to represent the same information content even though at a deeper level there are significant technical differences in the digital entities being implemented. This allows types defined in the UML model to be used directly in application schemas.

10.2.3.3 defines a set of conformance classes that will support applications whose requirements range from the minimum necessary to define data structures to full object implementation.

2.2 Conformance classes related to Application Schemas including Observations and Measurements

The conformance rules for Application Schemas in general are described in ISO 19109:2006. Application Schemas also claiming conformance to this International Standard shall also conform to the rules specified in Clauses 6-10 and pass all relevant test cases of the Abstract Test Suite in 10.2.3.3.

Depending on the characteristics of an Application Schema, 12 conformance classes are distinguished. Table 1 lists these classes and the corresponding Subclause of the Abstract Test Suite

Table 1 — Conformance classes related to Application Schemas including Observations and Measurements

Conformance class	Subclause
Generic observation interchange	A.1.1
Measurement interchange	A.1.1, A.1.2
Specialized observation interchange	A.1.1 - A.1.8
Coverage observation interchange	A.1.1, A.1.9, A.1.10
Temporal coverage observation interchange	A.1.1, A.1.11
Sampling feature interchange	A.2.1, A.2.2
Spatial sampling feature interchange	A.2.1 - A.2.3
Sampling point interchange	A.2.1 - A.2.4
Sampling curve interchange	A.2.1 - A.2.3, A.2.5
Sampling surface interchange	A.2.1 - A.2.3, A.2.6
Sampling solid interchange	A.2.1 - A.2.3, A.2.7
Specimen interchange	A.2.1 - A.2.3, A.2.8

4 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

4.1

application schema

conceptual schema for data required by one or more applications

[ISO 19101:2002]

4.2

coverage

feature that acts as a function to return values from its range for any direct position within its spatial, temporal or spatiotemporal domain

[ISO 19123:2005]

4.3

data type

specification of a value domain with operations allowed on values in this domain

[ISO/TS 19103:2005]

EXAMPLE Integer, Real, Boolean, String, Date (conversion of a date into a series of codes).

NOTE Data types include primitive predefined types and user-definable types. All instances of a data types lack identity.

4.4

domain feature

feature of a type defined within a particular application domain

NOTE This may be contrasted with observations and sampling features, which are features of types defined for cross-domain purposes.

4.5

feature

abstraction of real-world phenomena

[ISO 19101:2002]

NOTE A feature may occur as a type or an instance. Feature type or feature instance should be used when only one is meant.

4.6

feature type

class of features having common characteristics

[ISO 19109:2006]

4.7

measurand

particular quantity subject to measurement

[ISO/TS 19138:2006]

NOTE Specialization of observable **property-type**.

4.8

measure

value described using a numeric amount with a scale or using a scalar reference system

[ISO 19136:2007]

4.9

measurement

set of operations having the object of determining the value of a quantity

[ISO/TS 19101:2008]

4.10

observation

act of observing a **property**

NOTE: The goal of an observation may be to measure or otherwise determine the value of a property

4.11

observation procedure

method, algorithm or instrument, or system of these which may be used in making an **observation**

4.12

observation protocol

combination of a sampling strategy and an **observation procedure** used in making an **observation**

4.13

observation result

estimate of the value of a **property** determined through a known **procedure**

4.14

property <General Feature Model>

facet or attribute of an object referenced by a name

EXAMPLE Abby's car has the colour red, where "colour red" is a property of the car instance

4.15

property-type

characteristic of a feature type

[ISO 19109:2006]

EXAMPLE cars (a feature-type) all have a characteristic colour, where "colour" is a property-type

NOTE The value for an instance of a property-type may be estimated through an act of observation

NOTE In chemistry-related applications, the term 'determinand' or 'analyte' is often used.

4.16

sampling feature

feature, such as a station, transect, section or specimen, which is involved in making **observations** concerning a **domain feature**

NOTE A sampling feature is purely an artefact of the observational strategy, and has no significance independent of the observational campaign.

4.17

value

element of a type domain

[ISO/IEC 19501:2005].

NOTE 1 A value may consider a possible state of an object within a class or type (domain).

NOTE 2 A data value is an instance of a data type, a value without identity.

NOTE 3 A value may use one of a variety of scales including nominal, ordinal, ratio and interval, spatial and temporal. Primitive datatypes may be combined to form aggregate datatypes with aggregate values, including vectors, tensors and images

3D	Three Dimensional

5.2 Schema language

The conceptual schema specified in this International Standard is described using the Unified Modelling Language (UML) ISO/IEC 19501:2005, following the guidance of ISO/TS 19103:2005.

The UML is conformant with the profile described in ISO 19136:2007 Annex E. Use of this restricted idiom supports direct transformation into a GML Application Schema. ISO 19136:2007 introduces some additional stereotypes. In particular «FeatureType» implies that a class is an instance of the «metaclass» GF_FeatureType (ISO 19109:2006), and therefore represents a feature type.

The prose explanation of the model uses the term “property” to refer to both class attributes and association roles. This is consistent with the General Feature Model described in ISO 19109:2006. In the context of properties, the term “value” refers to either a literal (for attributes whose type is simple), or to an instance of the class providing the type of the attribute or target of the association. Within the explanation, the property names (property-types) are sometimes used as natural language words where this assists in constructing a readable text.

5.3 Model element names

This international standard specifies a model for observations using terminology that is based on current practice in a variety of scientific and technical disciplines. It is designed to apply across disciplines, so the best or “most neutral” term has been used in naming the classes, attributes and associations provided. The terminology does not, however, correspond precisely with any single discipline. As an aid to implementors, a mapping from the element names specified in this standard to common terminology in some application domains is provided in B.3.2.2.

5.4 External classes

Several model elements used in this schema are defined in other International Standards developed by ISO/TC 211. By convention within ISO/TC 211, names of UML classes, with the exception of basic data type classes, include a two or three letter prefix that identifies the standard and the UML package in which the class is defined. Table 2 lists the standards and packages in which UML classes used in this International Standard have been defined. UML classes defined in this International Standard have the prefix of CVT, GFI, OM, and SF. The prefix GFI is used for classes defined in this standard, but which are associated with the GF package in ISO 19109:2006. The prefix CVT is used for classes defined in this standard, but which are associated with the CV package in ISO 19123:2005.

Table 2 — Sources of UML classes

Prefix	International Standard	Package
CVT	This standard (A.2.8)	Temporal coverage
CV	ISO 19123:2005	Coverage
GFI	This standard (A.2.8)	General Feature Model general instance
DQ	ISO 19115:2003	Data Quality
GF	ISO 19109:2006	General Feature Model
GM	ISO 19107:2003	Geometry
LI	ISO 19115:2003	Data Quality
MD	ISO 19115:2003	Metadata Entity
OM	This standard	Observations and Measurements
SC	ISO 19111:2003	Coordinate reference systems
SF	This standard	Sampling features
TM	ISO 19108:2002	Temporal Schema

6 Fundamental characteristics of observations

6.1 The context for observations

6.1.1 Property evaluation

Properties of feature fall into two basic categories:

- Value assigned by some authority (e.g. name, price, legal boundary). These are exact.
- Value determined by application of an observation procedure (e.g. height, classification, colour). These are estimates, with a finite error associated with the value.

The error typically has a systematic component, which is similar for all estimates made using the same procedure, and a random component, associated with the particular application of the procedure. Where an application is concerned about potential errors in a property value, then the details of the act of observation which provided the estimate of the value are required.

Aside from the result, the details of the observation event are primarily of interest in applications where an evaluation of errors in the estimate of the value of a property is of concern. The observation could be considered to carry “property-level” instance metadata, which complements the dataset-level and feature-level metadata that have been conventionally considered (e.g. ISO 19115:2003).

6.1.2 Observation

An observation is an act that results in the estimation of the value of a feature property, and involves application of a specified procedure, such as a sensor, instrument, algorithm or process chain. The procedure may be applied in-situ, remotely, or ex-situ with respect to the sampling location. Use of a common model allows observation data using different procedures to be combined unambiguously. Observation details are also important for data discovery and for data quality estimation. Observation feature types are defined by the properties that support these applications.

An observation is an act associated with a discrete time instant or period through which a number, term or other symbol is assigned to a phenomenon D.3.5. The result of an observation is an estimate of the value of a property of some feature, so the details of the observation are metadata concerning the value of the feature property. The observation itself is also a feature, since it has properties and identity.

NOTE ISO 19115-2:2009 provides MI_Event, which plays a similar role to OM_Observation in the context of image capture.

6.1.3 Observation properties

An observation results in a value being assigned to a phenomenon. The phenomenon is a property of a feature, the latter being the feature of interest of the observation. The observation uses a procedure, which is often an instrument or sensor Error: Reference source not found but may be a process chain, human observer, an algorithm, a computation or simulator. The key idea is that the observation result is an estimate of the value of some property of the feature of interest, and the other observation properties provide context or metadata to support evaluation, interpretation and use of the result.

The relationship between the properties of an observation and those of its feature of interest is key to the semantics of the model. This is further elaborated in Annex D.3.

6.1.4 Observation location

The principal location of interest is usually associated with the ultimate feature-of-interest.

However, the location of the feature-of-interest may not be trivially available. For example: in remote sensing applications, a complex processing chain is required to geolocate the scene or swath; in feature-detection applications the initial observation may be made on a scene, but the detected entity, which is the ultimate feature of interest, occupies some location within it. The distinction between the proximate and ultimate feature of interest is a key consideration in these cases.

Other locations appear in various scenarios. Sub-sampling at locations within the feature-of-interest may occur. The procedure may involve a sensor located remotely from the ultimate feature of interest (e.g. remote sensing; or where specimens are removed from their sampling location and observed ex-situ). Furthermore, the location of the feature of interest may be time-dependent.

The model is generic. The geospatial location of the feature-of-interest may be of little or no interest for some observations (e.g. live specimens, observations made on non-located things like chemical species).

For these reasons, a generic Observation class does not have an inherent location property. Relevant location information should be provided by the feature of interest, or by the observation procedure, according to the specific scenario.

NOTE In contrast to spatial properties, some temporal properties are associated directly with an observation (6.2.2.2; 6.2.2.3). This is a consequence of the fact that an observation is kind of ‘event’ so its temporal characteristics are fundamental, rather than incidental.

6.1.5 Result types

Observation results may have many datatypes, including primitive types like category or measure, but also more complex types such as time, location and geometry. Complex results are obtained when the observed property requires multiple components for its encoding. Furthermore, if the property varies on the feature of interest, then the result is a coverage, whose domain extent is the extent of the feature. In a physical realisation, the result will typically be sampled discretely on the domain, and may be represented as a discrete coverage.

The result-type may be used as a basis for defining specialized observation types.

6.1.6 Measurements

In conventional measurement theory (e.g. Error: Reference source not found, D.3.5, D.3.5, D.3.5, D.3.5) the term “measurement” is used. However, a distinction between measurement and category-observation has been adopted in more recent work (D.3.5, D.3.5, D.3.5) so the term “observation” is used here for the general concept. “Measurement” may be reserved for cases where the result is a numeric quantity.

6.2 Observation schema

6.2.1 Packaging

The observation schema is organized into four packages containing five leaf packages corresponding to the conformance classes defined in Clause 2.2, with dependencies on several other packages from International Standards issued through ISO/TC 211, on the General Feature Instance package (Annex B.2) and the Temporal Coverage package (Annex B.3). The inter-package dependencies are shown in Figure 1. The Observation Core package is documented in this Clause. The Specialized Observation, Coverage Observation and Temporal Coverage Observation packages are documented in Clause 7.

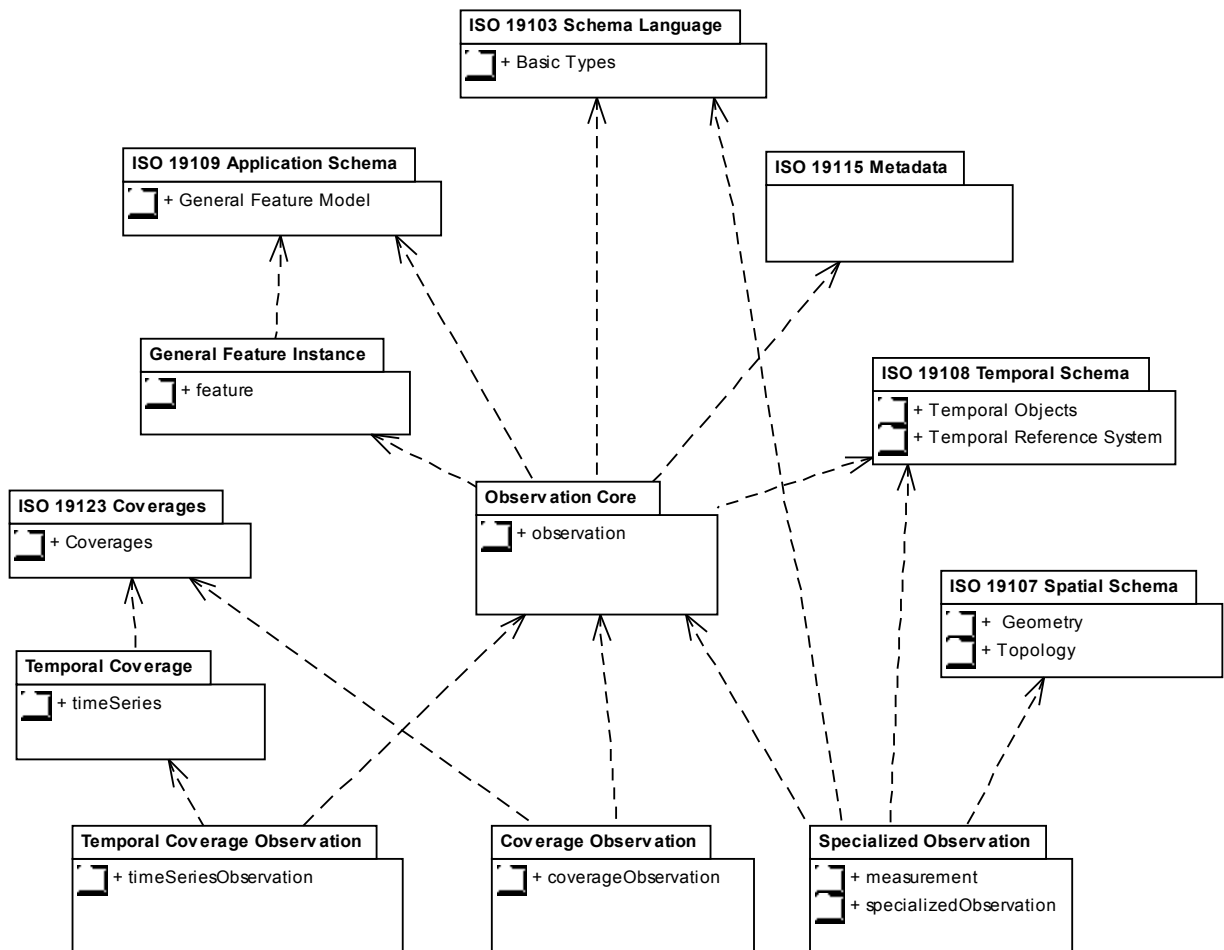

Figure 1 — Package dependencies of the observation schema

6.2.2 OM_Observation

6.2.2.1 General

The class *OM_Observation* (Figure 2) is an instance of the «metaclass» *GF_FeatureType* (ISO 19109:2006), which therefore represents a feature type. *OM_Observation* shall support five attributes and six associations, and shall be subject to four constraints.

EXAMPLE 4 Simulations may be used to estimate the values for phenomena in the future or past. The phenomenonTime is the time that the result applies to, while the resultTime is the time that the simulation was executed.

6.2.2.4 validTime

If present, the attribute *validTime:TM_Period* shall describe the time period during which the result is intended to be used.

NOTE This attribute is commonly required in forecasting applications.

6.2.2.5 parameter

If present, the attributes *parameter:NamedValue* shall describe an arbitrary event-specific parameter. This might be an environmental parameter, an instrument setting or input, or an event-specific sampling parameter that is not tightly bound to either the feature-of-interest (6.2.2.7) or to the observation procedure (6.2.2.10). To avoid ambiguity, there shall be no more than one parameter with the same name.

NOTE Parameters that are tightly bound to the procedure may be recorded as part of the procedure description.

In some contexts the *Observation::procedure* (6.2.2.10) is a generic or standard procedure, rather than an event-specific process. In this context, parameters bound to the observation act, such as instrument settings, calibrations or inputs, local position, detection limits, asset identifier, operator, may augment the description of a standard procedure.

EXAMPLE A time sequence of observations of water quality in a well may be made at variable depths within the well. While these may be associated with specimens taken from the well at this depth as the features-of-interest, a more common approach is to identify the well itself as the feature-of-interest, and add a “samplingDepth” parameter to the observation (Figure 3). The sampling depth is of secondary interest compared to the temporal variation of water quality at the site.

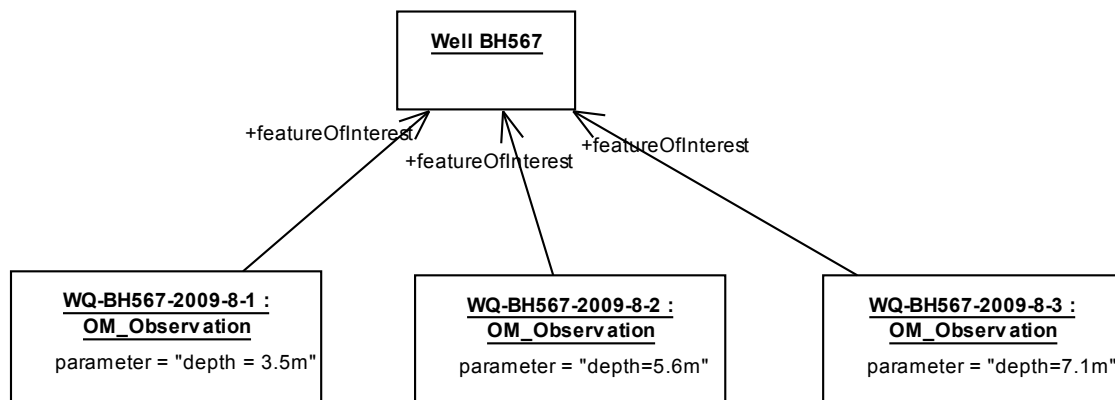

Figure 3 – (Example) Observation instances in the same well at different depths, described using the ‘parameter’ attribute

6.2.2.6 resultQuality

If present, the attributes *resultQuality:DQ_Element* shall describe the quality of the result (6.2.2.9). This instance-specific description complements the description of the observation procedure (6.2.2.10), which provides information concerning the quality of all observations using this procedure. Quality of a result may be assessed following the procedures in ISO 19114:2003. Multiple measures may be provided (ISO/TS 19138:2006).

6.2.2.7 Domain

The association *Domain* shall link the OM_Observation to the GFI_Feature (B.2.1) that is the subject of the observation and carries the observed property. This feature has the role *featureOfInterest* with respect to the

observation. This feature is the real-world object whose properties are under observation, or is a feature intended to sample the real-world object, as described in Clause 8 of this standard. An observation instance serves as a *propertyValueProvider* for its feature of interest.

6.2.2.8 Phenomenon

The association *Phenomenon* shall link the OM_Observation to the GFI_PropertyType (B.2.2) for which the OM_Observation:result (6.2.2.9) provides an estimate of its value. The property type has the role *observedProperty* with respect to the observation.

The observed property shall be a phenomenon associated with the type of the featureOfInterest.

NOTE An observed property may, but need not be modelled as a property (in the sense of the General Feature Model) in a formal application schema that defines the type of the feature of interest

The observed property supports semantic or thematic classification of observations, which is useful for discovery and data fusion.

6.2.2.9 Range

The association *Range* shall link the OM_Observation to the value generated by the procedure. The value has the role *result* with respect to the observation. The type of the result is shown as Any, since it may represent the value of any feature property.

NOTE OGC SWE Common provides a model suitable for describing many kinds of observation results.

The type of the observation result shall be consistent with the observed property, and the scale or scope for the value shall be consistent with the quantity or category type. If the observed property (6.2.2.8) is a spatial operation or function, the type of the result may be a coverage,

NOTE In some contexts, particularly in earth and environmental sciences, the term “observation” is used to refer to the *result* itself.

6.2.2.10 ProcessUsed

The association *ProcessUsed* shall link the OM_Observation to the OM_Process (6.2.3) used to generate the result. The process has the role *procedure* with respect to the observation. A process might be responsible for more than one *generatedObservation*.

The OM_Process shall be suitable for the observed property. As a corollary, details of the observed property are constrained by the procedure used.

EXAMPLE Observed radiance wavelength is determined by the response characteristics of the sensor.

A description of the observation procedure provides or implies an indication of the reliability or quality of the observation result.

6.2.2.11 Metadata

If present, the association *Metadata* shall link the OM_Observation to descriptive metadata.

6.2.2.12 Constraints - consistency with domain model

The type of the feature of interest is defined in an application schema (ISO 19109:2006). This may be part of a domain model, or may be from a cross-domain model, such as Sampling Features (clause 8). The feature type defines its set of properties. For consistency, the feature-of-interest shall carry the observed property as part of the definition of its type (e.g. Figure 4).

EXAMPLE A feature type “Pallet” may be defined as having the attribute “mass” of type “Measure”. An observation providing the value of this property shall have observedProperty=“mass”, the result shall be of type “Measure” and the scale (unit of measure) shall be suitable for mass measurements.

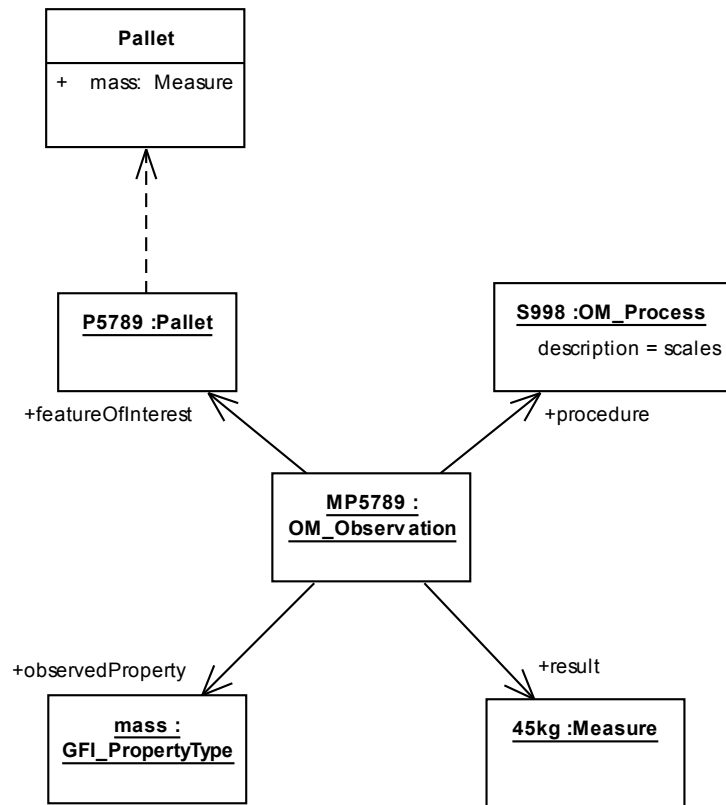

Figure 4 – (Example) An observation with consistent properties: the observed property (mass) is a phenomenon associated with the type of the feature of interest (Pallet) and the procedure and result type are also suitable

In the case of a feature property with internal structure (e.g. feature associations) the observed property may be of one component, or of a subset of elements, of the complete feature property. Hence, the observed property might not appear directly as a first order property in the type definition for the feature of interest, but shall appear within the structure of the feature type definition at some level (e.g. Figure 5).

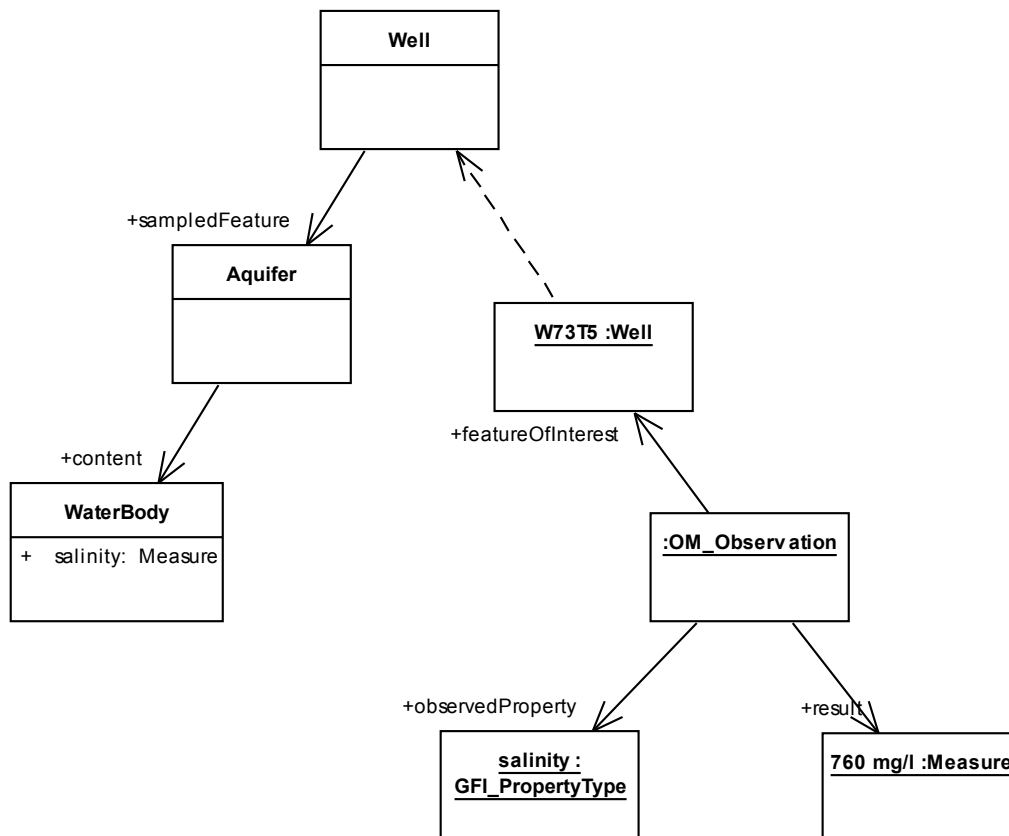

Figure 5 – (Example) An observation where the observed property is not a direct member of the type of the feature of interest

Other consistency constraints are that (a) the procedure shall be suitable for the observed property; (b) the result type shall be consistent with the observed property (e.g. Figure 4).

6.2.3 OM_Process

The class OM_Process (Figure 2) is an instance of the «metaclass» GF_FeatureType (ISO 19109:2006), which therefore represents a feature type. OM_Process is abstract, and has no attributes, operations or associations. It serves as the base class for observation processes. An instance of OM_Process is often an instrument or sensor, but may be a human observer, a simulator, or a process or algorithm applied to more primitive results used as inputs.

NOTE ISO 19115-2:2009 provides MI_Instrument, LE_Processing and LE_Algorithm, which could all be modelled as specializations of OM_Process. OGC SensorML D.3.5 provides a model which is suitable for many observation procedures.

6.2.4 ObservationContext

6.2.4.1 General

Some observations depend on other observations to provide context which is important, sometimes essential, in understanding the result. These dependencies are stronger than mere spatio-temporal coincidences, requiring explicit representation. If present, the association class class *ObservationContext* (Figure 2) shall link a OM_Observation to another OM_Observation, with the role name relatedObservation for the target. It shall support one attribute.

EXAMPLES Some examples include the conditions associated with experimental replicates (e.g., experimental plots and treatments used), biotic factors (e.g., ecological community), interactions among features (e.g., predator-prey), or other temporary relationships occurring at the time of observation that are not inherent to the observed features

themselves (i.e., they change over time), or the related observation may provide input to a process that generates a new result.

This association complements the Intention association which describes relationships between a sampling feature and domain features.

6.2.4.2 role

The attribute *role:GenericName* shall describe the relationship of the target OM_Observation to the source OM_Observation.

6.2.5 NamedValue

6.2.5.1 General

The class *NamedValue* provides for a generic soft-typed parameter value. *NamedValue* shall support two attributes.

6.2.5.2 name

The attribute *name:GenericName* shall indicate the meaning of the named value. Its value should be taken from a well-governed source if possible.

EXAMPLES When used as the value of an Observation::parameter, the name might take values like 'procedureOperator', 'detectionLimit', 'amplifierGain', 'samplingDepth'.

6.2.5.3 value

The attribute *value:Any* shall provide the value. The type Any should be substituted by a suitable concrete type, such as CI_ResponsibleParty or Measure.

6.3 Use of the observation model

The Observation model takes a data-user-centric viewpoint, emphasizing the semantics of the feature-of-interest and its properties. This contrasts with Sensor oriented models, which take a process- and thus provider-centric viewpoint.

An observation is a property-value-provider for a feature of interest. Aside from the result, the details of the observation event are primarily of interest in applications where an evaluation of errors in the estimate of the value of a property is of concern. The Observation could be considered to carry "property-level" instance metadata, complementing the dataset-level and feature-level metadata that have been conventionally considered (e.g. ISO 19115:2003).

Additional discussion of the application of the observation and sampling models, and nuances within these, is provided in C.2.6.

7 Specialized observations

7.1 Classification of observation by result type

The observation result type shall be suitable for the observed property. The observation type may be classified by the type of the result. Two groups of specialized observations may be distinguished:

- a) Observations for which the result of a single observation may be either single-valued or multi-valued, but, if there are multiple values, those values do not vary with either spatial position or time during the duration of the observation
- b) Observations for which the result of a single observation contains multiple values that vary with either spatial position, time, or both, during the duration of the observation.

7.2 Observations whose result is constant

7.2.1 General

Where a property of the feature of interest is spatially and temporally invariant during the period of an observation, the corresponding observation result is a scalar (e.g. mass, length, temperature), or a record whose components correspond to a thematic decomposition of the observed property (e.g. bands of a spectrum, components of a wind-velocity vector, components of a stress tensor, elements of a geometry). Where a standard model for the observed property is available, this may be used for the result (e.g. observations of position, shape, or time should use GM_Object and TM_Object).

7.2.2 Taxonomy of observation types whose result is constant

Observation types with results that are internally invariant with respect to space or time are in the Specialized Observation package and are shown in Figure 6:

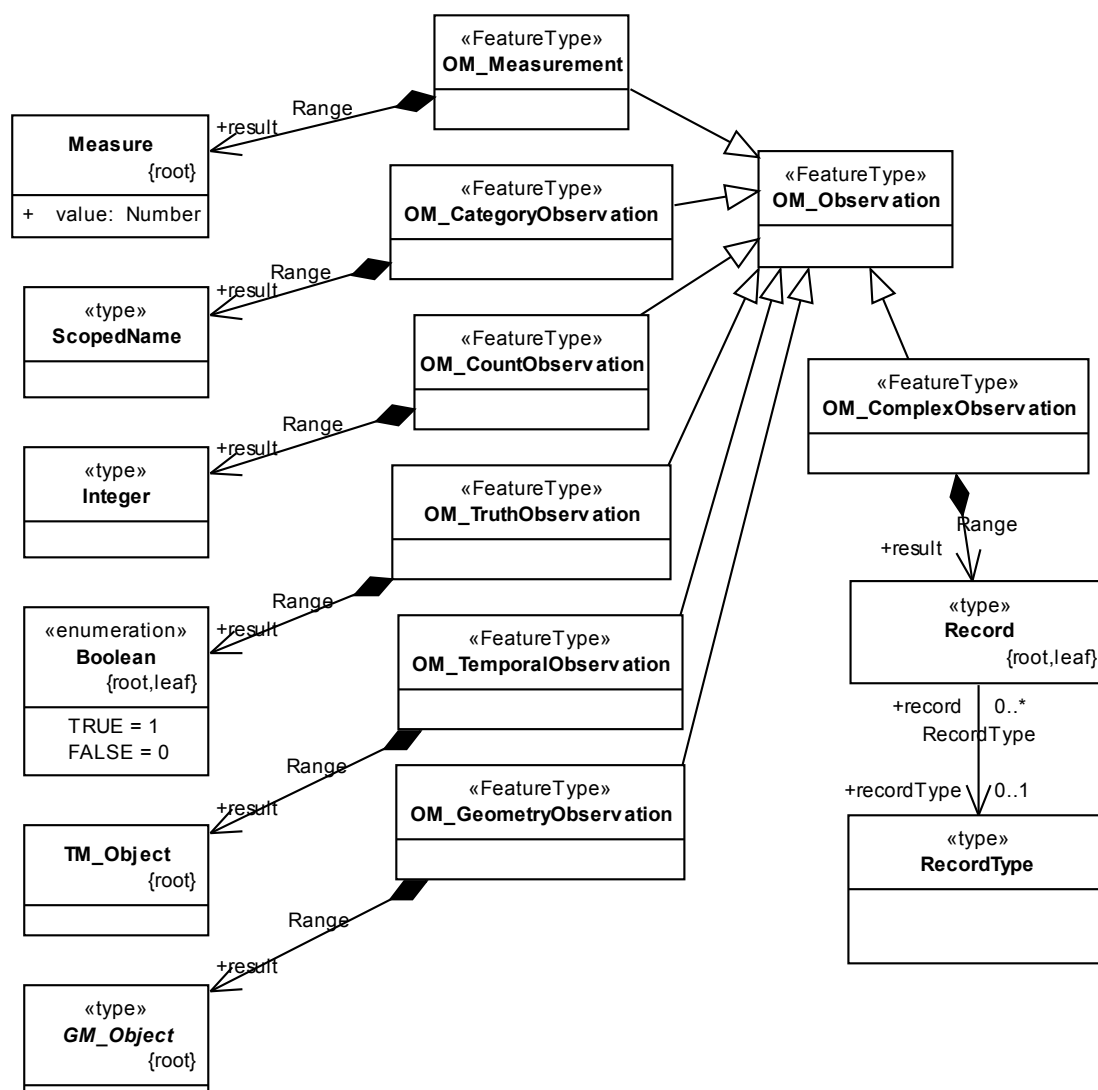

Figure 6 – Specializations of observation by result type

NOTE The classes Measure, ScopedName, Integer, Boolean, Record and RecordType are defined in ISO TS 19103, TM_Object in ISO 19108:2002 and GM_Object in ISO 19107:2003.

For each specialized observation class, the target of the association named 'Range' with the role-name 'result' shall be redefined as indicated in Figure 6 and Table 3.

Table 3 – Result-types for specialized observations

Specialized observation class	Result type	Example
OM_Measurement	Measure	A measurement of "mass" (property-type) of "the seventh banana" (feature-of-interest) using the "kitchen scales" (procedure) had the result "150g"
OM_CategoryObservation	ScopedName	A category observation of the "taxon" (property-type) of "specimen 123" (feature-of-interest) by "Amy Bachrach" (procedure) had the result "Eucalyptus caesia" (from the Flora of Australia)
OM_CountObservation	Integer	A count observation of "the number of votes cast" (property-type) at "the municipal election" (feature-of-interest) using the "electronic voting machine tally" (procedure) had the result "3542"
OM_TruthObservation	Boolean	A truth observation of "presence" (property-type) of "intruder" (feature-of-interest) using the "CCTV" (procedure) had the result "false"
OM_TemporalObservation	TM_Object	A temporal observation of "duration" (property-type) for "Usain Bolt 100m dash" (feature-of-interest) using the "stop watch" (procedure) had the result "9.6s"
OM_GeometryObservation	GM_Object	A geometry observation of "perimeter" (property-type) for "plot 987" (feature-of-interest) using the "field survey GHJ" (procedure) had the result "(... description of polygon ...)"
OM_ComplexObservation	Record (ISO 19103:2005)	A complex observation of "major element composition" (property-type) for "specimen h8j" (feature-of-interest) using the "ICPMS" (procedure) had the result "(... array of element proportions ...)"
* If the observedProperty of a temporal observation is 'occurrence time' then the value of the result will generally be the same as the value of the phenomenonTime		

7.3 Observations whose result varies

7.3.1 General

Where the type of a feature allows for a property that is dependent on some parameter, then the value of the property is a *function* of this parameter.

EXAMPLE The length of a rail varies with temperature.

If the variation is temporal or spatial, then the function is a *coverage* (CV_Coverage—ISO 19123:2005) whose domain extent is the spatio-temporal extent of the feature. The value of a corresponding observation result shall therefore be a function or coverage, respectively. In practice, the observation will *sample* the relevant axis of the target feature, so the observation result is usually represented as a *discrete* function or coverage (CV_DiscreteCoverage).

The target feature may have many observations made on it using different sampling regimes, so the sampling regime is associated with the act of observation, rather than being inherent in the feature of interest. This may be accommodated by the decomposition of the domain geometry (i.e. the CV_DomainObject elements) in the observation *result*. The decomposition of the domain geometry in the result provides an intrinsic element of the overall observation protocol

NOTE The sampling regime may also be accommodated by multiple observations on a complex of sampling features (Error: Reference source not found).

EXAMPLE The colour of a scene varies with position. The result of an observation of the property "colour" of the scene is a coverage. Each domain element is a pixel whose index allows the spatial location within the scene to be obtained.

EXAMPLE Many properties of an observation-well vary along its length, including rock-type, orientation, permeability etc. These are conventionally encoded as "logs", with different sampling regimes. Each well-log is a coverage whose domain is the curve describing the shape of the well. The domain is sampled with elements whose location is described in terms of 1-D position measured along the well axis.

A simple case concerns sampling a property at points on an extensive feature. The observation result is a set of point-value pairs (CV_PointValuePair—ISO 19123:2005).

EXAMPLE Temperature may be sampled using an array of weather stations. The temperature field of the region covered by the array may be represented as a discrete point coverage, whose domain-elements correspond to the station locations.

An important case concerns monitoring a time-varying property of a persistent feature by sampling at discrete points in time. The observation result is a set of time-value pairs (either CV_PointValuePair, in which the point geometry uses a temporal reference system, or CVT_TimeInstantValuePair—Annex B.3.2).

EXAMPLE An air- or water-quality monitoring station observes properties such as ozone, turbidity, etc. The instantaneous value is a scalar concentration or index value. However, the value is time-dependent. The value may be expressed as a coverage whose domain is the period of interest. This is usually described as a time series, which is a discrete time coverage.

The feature of interest may be naturally structured into elements, such as a road network composed of road-segments, or a state composed of administrative areas at a finer scale, or a farm composed of fields. Observation of a property of these features may capture its variation as a function of the sub-features. In these cases the standard members of the target feature are responsible for decomposition of the domain geometry.

7.3.2 Taxonomy of coverage observation types

Observation types with variable results are shown in Figure 7.

For each specialized observation class whose result varies, the target of the association named 'Range' with the role-name 'result' shall be redefined as indicated in Figure 7 and Table 4.

Table 4 – Result-types for specialized observations

Specialized observation class	Result type
OM_DiscreteCoverageObservation	CV_DiscreteCoverage
OM_DiscretePointCoverageObservation	CV_DiscretePointCoverage
OM_DiscreteTimeSeriesObservation	CVT_DiscreteTimeInstantCoverage (B.3.1)

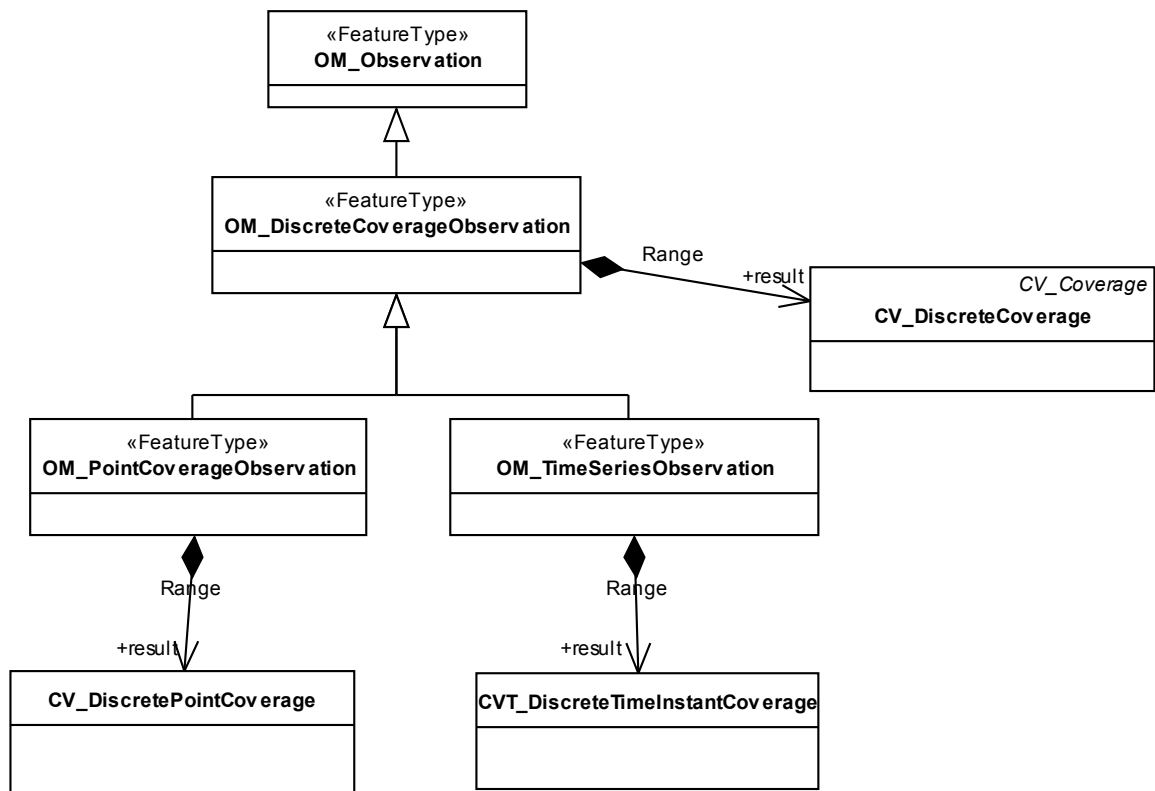

Figure 7 – Specialization of observations with coverage-valued results

8 Fundamental characteristics of sampling features

8.1 The context for sampling

8.1.1 Proximate vs. ultimate feature of interest

8.1.1.1 Introduction

The observation model maps the result of the application of a procedure to a subject, which plays the role of feature-of-interest of the observation (Clause 6). However, the proximate feature of interest of an observation may not be the ultimate domain-specific feature whose properties are of interest in the investigation of which the observation is a part. There are two circumstances that can lead to this: (i) the observation does not obtain values for the whole of a domain feature; (ii) the observation procedure obtains values for properties that are not characteristic of the type of the ultimate feature. Furthermore, in some practical situations, both differences apply.

8.1.1.2 Proximate feature of interest embodies a sample design

For various reasons the domain feature may not be fully accessible. In such circumstances, the procedure for estimating the value of a property of the domain feature involves sampling in representative locations. Then the procedure for transforming a property value observed on the sample to an estimate of the property on the ultimate feature of interest depends on the sample design.

EXAMPLE The chemistry of water in underground aquifer is sampled at one or more positions in a well or bore.

EXAMPLE The magnetic field of the earth is sampled at positions along a flight-line.

EXAMPLE The structure of a rock mass is observed on a cross-section exposed in a river bank.

8.1.1.3 Observed property is a proxy

The procedure for obtaining values of the property of interest may be indirect, relying on direct observation of a more convenient parameter which is a proxy for the property of interest. Application of an algorithm or processing chain obtains an estimate of the ultimate property of interest.

The observation model requires that the feature of interest of the initial observation be of a type that carries the observed property within its properties. Thus, if the proxy property is not a member of the ultimate feature of interest, a proxy feature with a suitable model shall be involved.

EXAMPLE A remote sensing observation may obtain the reflectance colour, when the investigation is actually interested in vegetation type and quality. The feature which contains reflectance colour is a scene or swath, while the feature carrying vegetation properties is a parcel or tract.

8.1.1.4 Combination

These variations may be combined if (i) exhaustive observation of the domain feature is impractical, and (ii) direct measurement is of a proxy property.

EXAMPLE For certain styles of mineralization, the gold concentration of rocks in a region might be estimated through measurement of a related element (e.g. copper), in a specimen of gravel collected from a stream that drains part of the region. The gravel samples the rocks in the catchment of the stream, i.e. in the stream bed and upslope.

8.1.2 Role of sampling features

Sampling features are artefacts of an observational strategy, and have no significant function outside of their role in the observation process. The physical characteristics of the features themselves are of little interest, except perhaps to the manager of a sampling campaign.

EXAMPLE A “station” is essentially an identifiable locality where a sensor system or procedure may be deployed and an observation made. In the context of the observation model, it connotes the “world in the vicinity of the station”, so the observed properties relate to the physical medium at the station, and not to any physical artefact such as a mooring, buoy, benchmark, monument, well, etc.

NOTE A transient sampling feature, such as a ships-track or flight-line, may be identified and described, but is unlikely to be revisited exactly.

A sampling feature is intended to sample some feature of interest in an application domain. However, in some cases the identity, and even the exact type, of the sampled feature may not be known when observations are made using the sampling features.

8.1.3 Classification of sampling features

A small number of sampling patterns are common across disciplines in observational science. These provide a basis for processing and portrayal tools which are similar across domains, and depend particularly on the geometry of the sample design. Common names for sampling features include specimen, station, profile, transect, path, swath, and scene. Spatial sampling is classified primarily by the topological dimension. The generic characteristics of sampling features are defined in this Clause; spatial samples of various dimensions in Clause 9; and specimens in Clause 10.

8.2 Sampling Schema

8.2.1 Packaging

The sampling schema is organized into three packages containing seven leaf packages corresponding to the conformance classes defined in Clause 2.2, with dependencies on the observation schema (Clause 6), the general feature instance package (Annex B.2), and on several other packages from International Standards issued through ISO/TC 211. The inter-package dependencies are shown in Figure 5. The Sampling Core package is documented in this Clause. The Sampling Manifold package is documented in Clause 9 and the Specimen package in Clause 10.

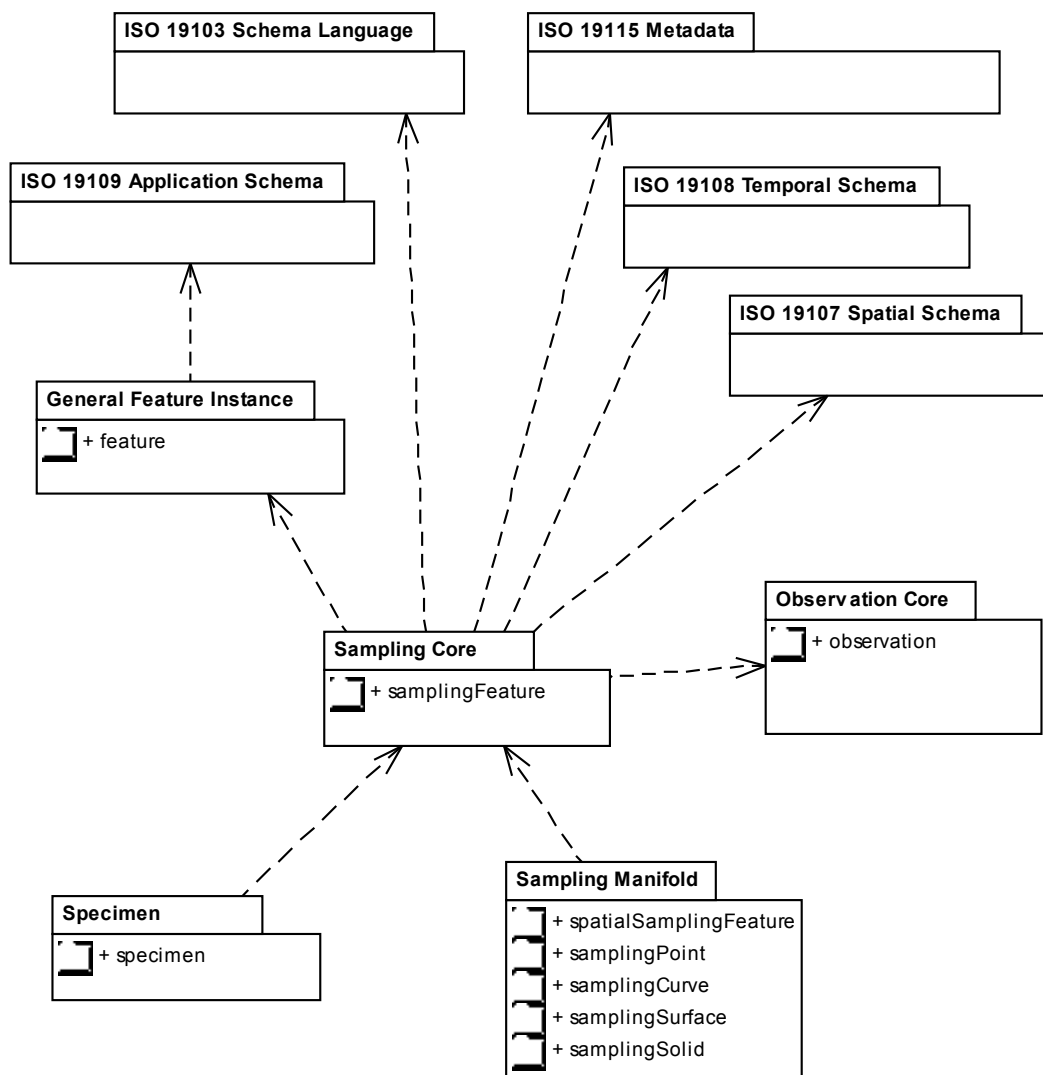

Figure 8 — Package dependencies of the sampling feature schema

8.2.2 SF_SamplingFeature

8.2.2.1 General

The abstract class *SF_SamplingFeature* (Figure 9) is an instance of the «metaclass» *GF_FeatureType* (ISO 19109:2006), which therefore represents a feature type. *SF_SamplingFeature* shall support two attributes and three associations, and shall be subject to one constraint.

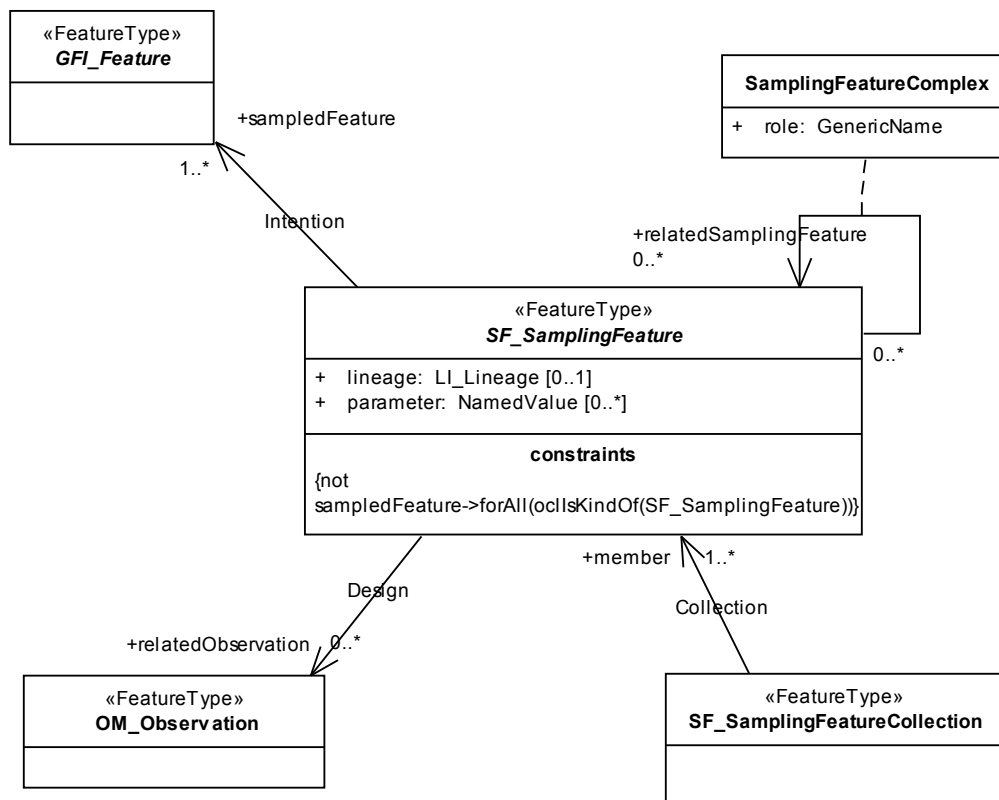

Figure 9 — Sampling feature core

8.2.2.2 parameter

If present, the attributes *parameter:NamedValue* shall describe an arbitrary parameter associated with the SF_SamplingFeature. This might be a parameter that qualifies the interaction with the sampled feature, or an environmental parameter associated with the sampling process.

8.2.2.3 lineage

If present, the attribute *lineage:LI_Lineage* shall describe the history and provenance of the SF_SamplingFeature. This might include information relating to the handling of the specimen, or details of the survey procedure of a spatial sampling feature.

8.2.2.4 Intention

A sampling feature is established in order to make observations concerning some domain feature. The association *Intention* shall link the SF_SamplingFeature to the feature which the sampling feature was designed to sample. The target of this association has the role *sampledFeature* with respect to the sampling feature, and shall not be a sampling feature. It is usually a real-world feature from an application domain (Figure 5; Figure 10).

EXAMPLE A profile typically samples a water- or atmospheric-column; a well samples the water in an aquifer; a tissue specimen samples a part of an organism

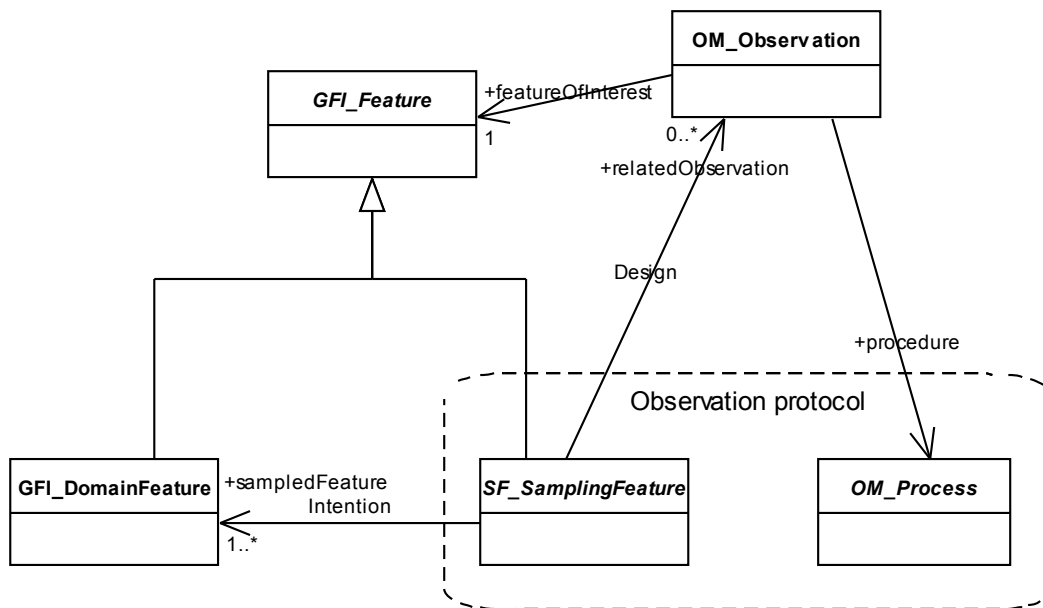

Figure 10 – (Informative) Relationship between sampling and domain features. Each may appear as the feature of interest. If a sampling feature is involved, it samples a feature of a type defined in an application schema. Also see Figure 5. The sampling feature together with the observation procedure describe the observation protocol.

NOTE GFI_DomainFeature is informative only. It stands for all feature types that are not sampling features.

8.2.2.5 Design

Sampling features are distinctive compared with other features from application domains by having navigable associations to observations. If present, the association *Design* shall link the SF_SamplingFeature to an OM_Observation that was made utilizing the sampling feature, and the description of the sampling feature provides an intrinsic element of the observation protocol, along with the observation procedure (6.2.2.10) and the decomposition of the domain geometry in the case of a coverage-valued result (7.3.1). The OM_Observation has the role *relatedObservation* with respect to the sampling feature. Multiple observations may be made on a single sampling feature.

8.2.2.6 Constraint

A constraint on OM_Observation is that its observed property is a member property of the feature of interest either directly or transitively. Where the feature of interest of an observation is a sampling feature, the observed property shall be a member of the sampling feature or of the sampled feature.

Where the identity or type of the sampled feature is not be known prior to processing the observation result the constraint cannot be enforced immediately.

8.2.3 SamplingFeatureComplex

8.2.3.1 General

Sampling features are frequently related to each other, as parts of complexes, through sub-sampling, and in other ways. If present, the association class class *SamplingFeatureComplex* (Figure 9) shall link a SF_SamplingFeature to another SF_SamplingFeature. It shall support one attribute.

EXAMPLES sampling points are often located along a sampling curve; specimens are usually obtained from a sampling point; pixels are part of a scene; stations are often part of an array.

This association complements the Intention association which describes relationships between a sampling feature and domain features.

8.2.3.2 role

The attribute *role:GenericName* shall describe the relationship of the target *SF_SamplingFeature* to the source *SF_SamplingFeature*.

8.2.4 SF_SamplingFeatureCollection

8.2.4.1 General

The class *SF_SamplingFeatureCollection* (Figure 9) is an instance of the «metaclass» *GF_FeatureType* (ISO 19109:2006), which therefore represents a feature type. *SF_SamplingFeatureCollection* shall support one association.

8.2.4.2 Collection

The association *Collection* shall link a *SF_SamplingFeatureCollection* to member *SF_SamplingFeatures*.

9 Spatial sampling features

9.1 The context for spatial sampling features

When observations are made to estimate properties of a geospatial feature, in particular where the value of a property varies within the scope of the feature, a spatial sampling feature is used. Depending on accessibility and on the nature of the expected property variation, the sampling feature may be extensive in one, two or three spatial dimensions. Processing and visualization methods are often dependent on the topological dimension of the sampling manifold, so this provides a natural classification system for sampling features.

This classification follows common practice in focussing on conventional spatial dimensions. Properties observed on sampling features may be time-dependent, but the temporal axis does not generally contribute to the classification of sampling feature classes. Sampling feature identity is usually less time-dependent than is the property value.

9.2 Spatial sampling feature schema

9.2.1 SF_SpatialSamplingFeature

9.2.1.1 General

The class *SF_SpatialSamplingFeature* (Figure 11) is an instance of the «metaclass» *GF_FeatureType* (ISO 19109:2006), which therefore represents a feature type. *SF_SpatialSamplingFeature* shall support one attribute and two associations.

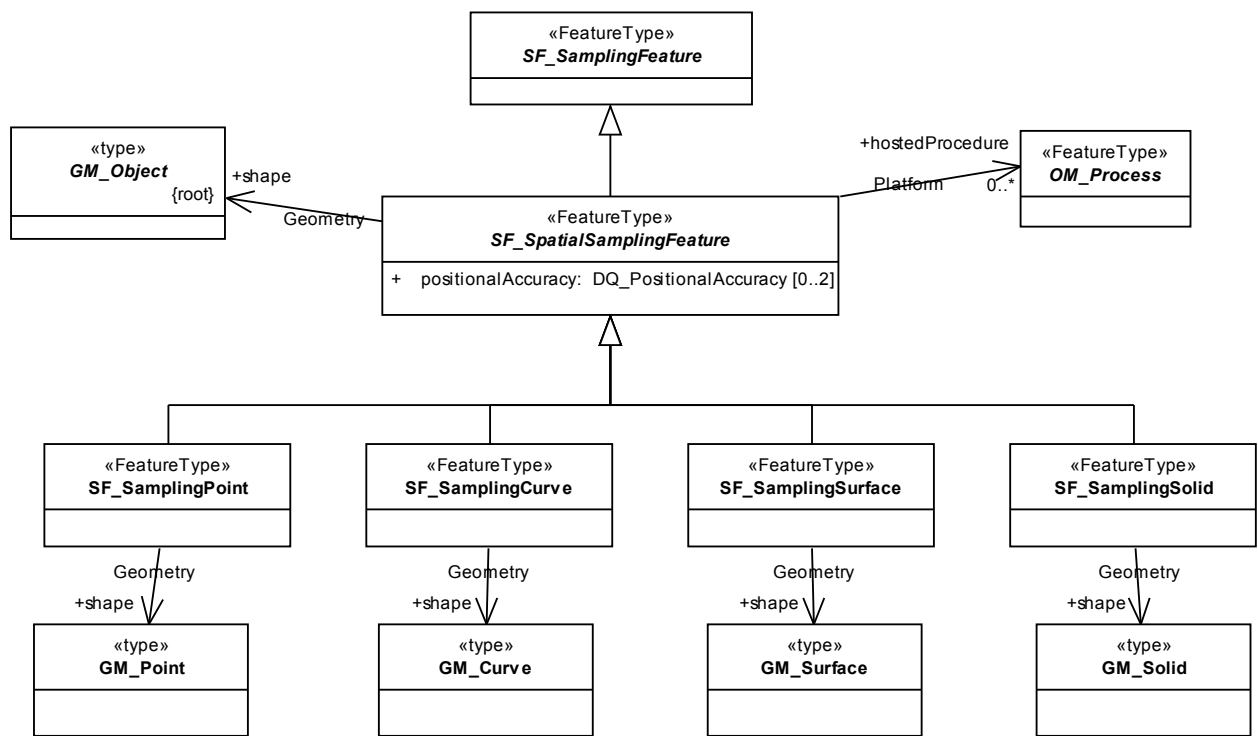

Figure 11— Spatial sampling features

9.2.1.2 positionalAccuracy

Positioning metadata is commonly associated with sampling features defined in the context of field surveys. If present, *positionalAccuracy:DQ_PositionalAccuracy* shall describe the accuracy of the positioning of the sampling feature. Up to two instances of the attribute support the independent description of horizontal and vertical accuracy.

9.2.1.3 Geometry

The association *Geometry* shall link a *SF_SpatialSamplingFeature* to a *GM_Object* that describes its shape.

9.2.1.4 Platform

A common role for a spatial sampling feature is to host instruments or procedures deployed repetitively or permanently. If present, the association *Platform* shall link the *SF_SpatialSamplingFeature* to an *OM_Process* deployed at it. The *OM_Process* has the role *hostedProcedure* with respect to the sampling feature.

9.2.2 Taxonomy of spatial sampling features

Concrete spatial sampling feature classes shall be distinguished on the basis of the type of the shape property, as shown in Figure 11 and Table 5.

Table 5 – Shape-types for specialized spatial sampling features

Specialized spatial sampling feature	Shape type
SF_SamplingPoint	GM_Point
SF_SamplingCurve	GM_Curve
SF_SamplingSurface	GM_Surface
SF_SamplingSolid	GM_Solid

9.3 Decomposition of extensive sampling features for observations

The shape of a spatially extensive sampling feature (sampling-curve, -surface or -solid) defines a manifold within which a varying property may be characterized, and hence within which subsampling may be undertaken. The shape provides a complete sampling domain, but does not specify any particular decomposition. Sub-sampling may be described using related sampling features, or as domain elements of a discrete coverage representation of the variation of a property within the sampling feature. The shape of the sampling feature is the context for domain decomposition. Where spatial sampling is involved, then both the sampling feature shape and its discretization as described in the domain of the coverage that comprises the observation result are required to describe the overall observation protocol.

EXAMPLE 1 Logs of different properties along a well or borehole may use different intervals, and sub-samples may be either spatially instantaneous, or averaged in some way over an interval. The position of the samples may be conveniently described in terms of offsets in a linear coordinate reference system that is defined by the shape of the well axis.

Time dependent properties may be observed if a sampling feature is temporally-persistent. .

EXAMPLE 2 The temperature of the atmosphere at a weather station varies as a function of time.

Properties observed using a sampling feature may depend on non-spatio-temporal axes.

EXAMPLE 3 The density of a specimen varies as a function of temperature.

9.4 Common names for sampling features (informative)

Some common names for sampling features used in various application domains include Borehole, Flightline, Interval, Lidar Cloud, Map Horizon, Microscope Slide, Mine Level, Mine, Observation Well, Profile, Pulp, Quadrat, Scene, Section, ShipsTrack, Spot, Station, Swath, Trajectory, Traverse, etc. These are mapped to the standard sampling feature classes in Figure 12. Note that these mappings are informative only, and may not match some applications.

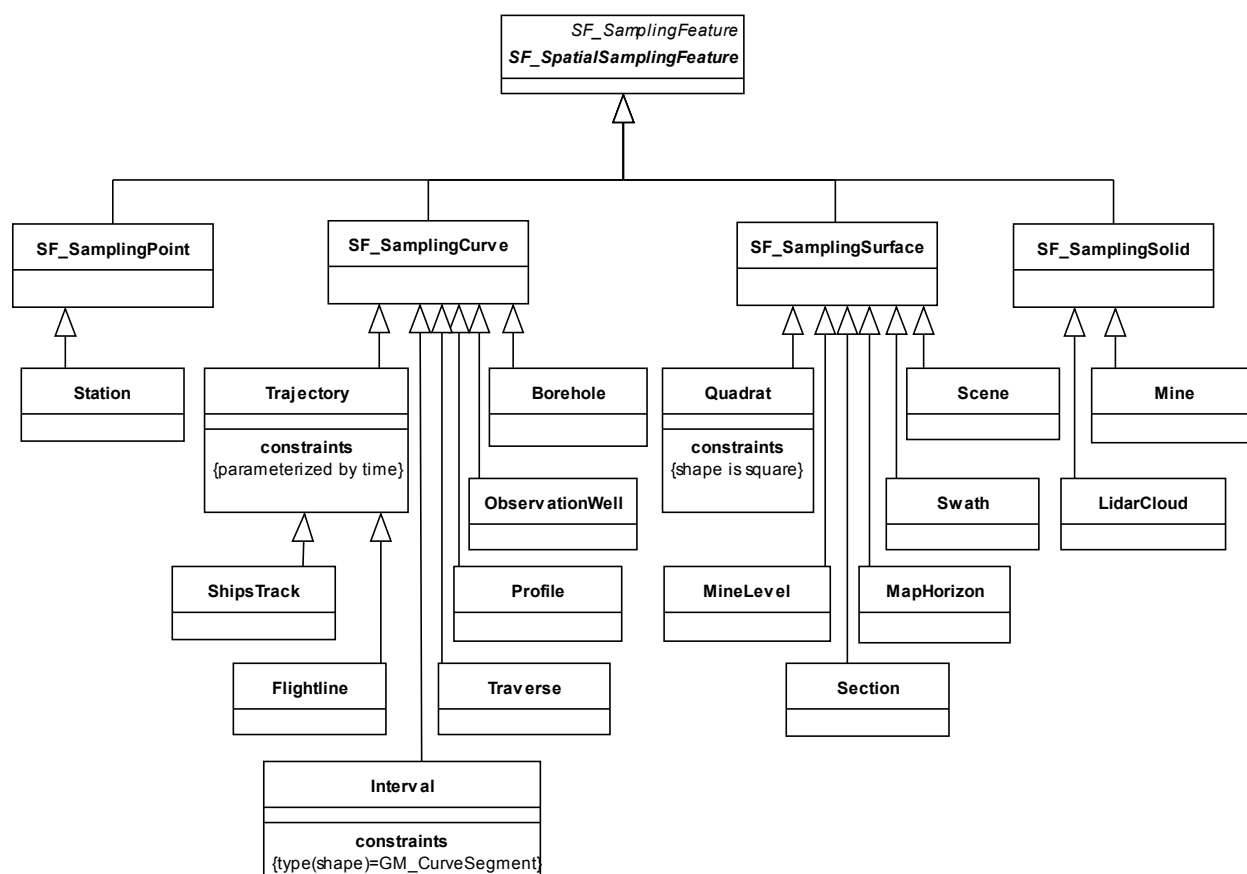

Figure 12 — (Informative) Common terms for spatially extensive sampling features, (i.e. the classes whose names are unprefixd)

10 Specimens

10.1 The context for specimens

A Specimen is a physical sample, obtained for observation(s) carried out *ex situ*, sometimes in a laboratory.

10.2 Specimen schema

10.2.1 SF_Specimen

10.2.1.1 General

The class *SF_Specimen* (Figure 13) is a specialized *SF_SamplingFeature*. *SF_Specimen* shall support seven attributes and one association

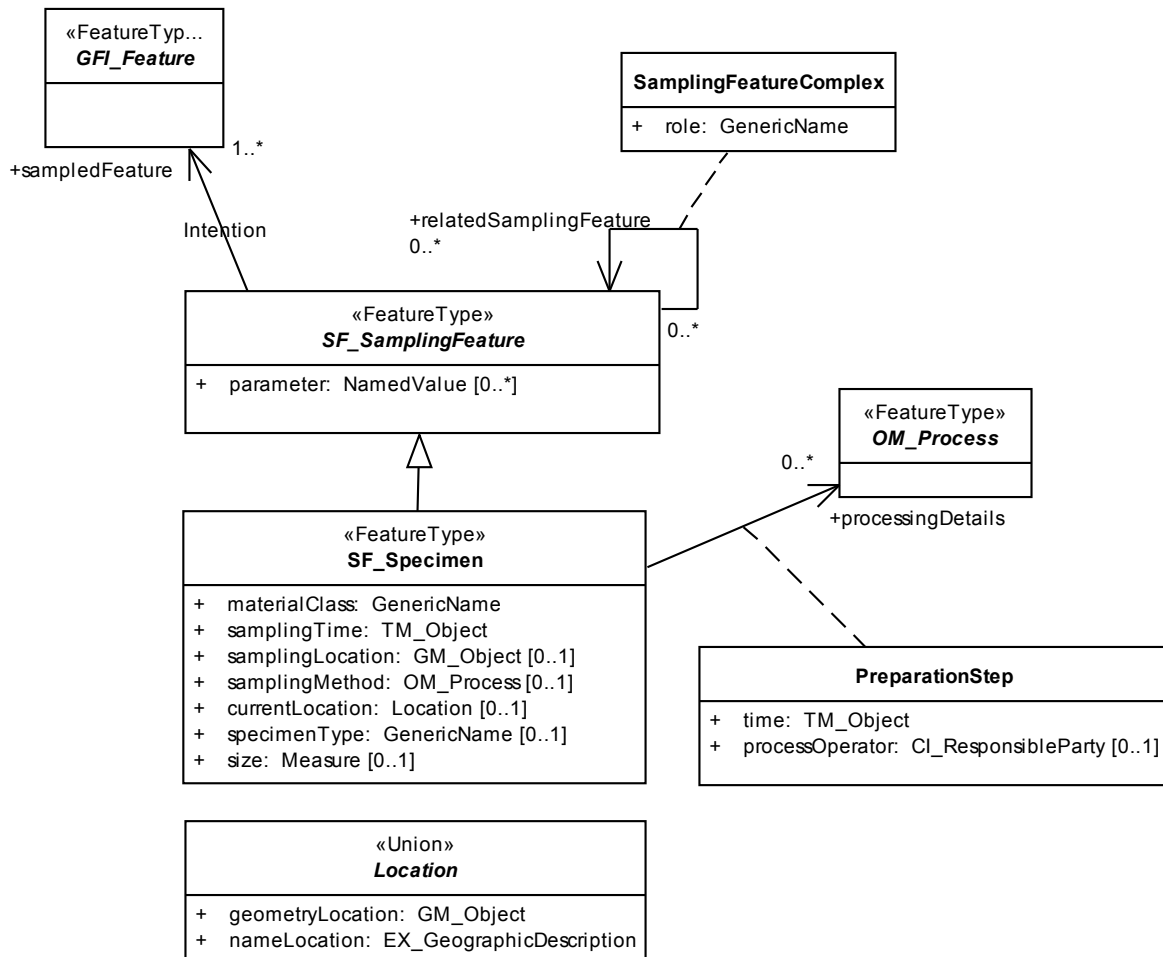

Figure 13— Specimen model

10.2.1.2 materialClass

The attribute *materialClass:GenericName* shall provide a basic classification of the material type of the specimen.

EXAMPLE soil, water, rock, aqueous, liquid, tissue, vegetation, food.

10.2.1.3 samplingTime

The attribute *samplingTime:TM_Object* shall record when the specimen was retrieved from the sampled feature.

10.2.1.4 samplingLocation

If present, the attribute *samplingLocation:GM_Object* shall describe the location from where the specimen was obtained.

NOTE Where a specimen has a relatedSamplingFeature whose location provides an unambiguous location then this attribute is not required. However, if the specific sampling location within the sampledFeature is important, then this attribute supports its description.

10.2.1.5 samplingMethod

If present, the attribute *samplingMethod:OM_Process* shall describe the method used to obtain the specimen from its sampledFeature.

10.2.1.6 currentLocation

If present, the attribute *currentLocation:Location* shall describe the location of a physical specimen. This may be a storage location, such as a shelf in a warehouse or a drawer in a museum.

NOTE If a specimen no longer exists, for example it was destroyed in connection with an observation act, then the *currentLocation* should be omitted or carry a suitable null indicator.

10.2.1.7 specimenType

If present, the attribute *specimenType:GenericName* shall describe the basic form of the specimen.

EXAMPLE polished section; core; pulp; solution.

10.2.1.8 size

If present, the attribute *size:Measure* shall describe a physical extent of the specimen. This may be length, mass, volume, etc as appropriate for the specimen instance and its material class.

10.2.2 PreparationStep

10.2.2.1 General

In many applications specimen preparation procedures are applied to the material prior to its use in an observation. The class *PreparationStep* (Figure 13) shall link a *SF_Specimen* to a *OM_Process* that describes a phase of the specimen preparation. It shall support one attribute.

10.2.2.2 time

The attribute *time:TM_Object* shall describe the time that the *OM_Process* was applied to the *SFN_Specimen*. It supports ordering of preparation steps.

10.2.2.3 processOperator

If present, the attribute *processOperator:CI_ResponsibleParty* shall describe the operator of the process involved in the preparation step.

10.2.3 Location

10.2.3.1 General

Location (Figure 13) is a union class (choice) that shall support two attributes.

10.2.3.2 geometryLocation

The attribute *geometryLocation:GM_Object* shall select a geometric representation of the location.

10.2.3.3 nameLocation

The attribute *nameLocation:EX_GeographicDescription* shall select a description of the location using text or an identifier.

Annex A

(normative)

Abstract test suite

A.1 Abstract tests for observation interchange

A.1.1 Observation interchange

The observation interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of OM_Observation.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 6.
- d) Test Type: Capability.

A.1.2 Measurement interchange

The measurement interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of OM_Measurement.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 7.2.2.
- d) Test Type: Capability.

A.1.3 Category observation interchange

The category observation interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of OM_CategoryObservation.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 7.2.2.
- d) Test Type: Capability.

A.1.4 Count observation interchange

The count observation interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of OM_CountObservation.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 7.2.2.

- d) Test Type: Capability.

A.1.5 Truth observation interchange

The truth observation interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of OM_TruthObservation.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 7.2.2.
- d) Test Type: Capability.

A.1.6 Temporal observation interchange

The temporal observation interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of OM_TemporalObservation.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 7.2.2.
- d) Test Type: Capability.

A.1.7 Geometry observation interchange

The geometry observation interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of OM_GeometryObservation.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 7.2.2.
- d) Test Type: Capability.

A.1.8 Complex observation interchange

The complex observation interchange test consists of the following:

- e) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of OM_ComplexObservation.
- f) Test Method: Inspect the documentation of the interchange schema.
- g) Reference: ISO 19156, Clause 7.2.2.
- h) Test Type: Capability.

A.1.9 Discrete coverage observation interchange

The discrete coverage observation interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of OM_DiscreteCoverageObservation.

- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 7.3.2.
- d) Test Type: Capability.

A.1.10 Point coverage observation interchange

The point coverage observation interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of OM_PointCoverageObservation.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 7.3.2.
- d) Test Type: Capability.

A.1.11 Time series observation interchange

The time series observation interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of OM_TimeSeriesObservation.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 7.3.2.
- d) Test Type: Capability.

A.2 Abstract tests for sampling feature interchange

A.2.1 Sampling feature interchange

The sampling feature interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of a concrete subclass of SF_SamplingFeature.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clauses 8, 9, 10.
- d) Test Type: Capability.

A.2.2 Sampling feature collection interchange

The sampling feature collection interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of SF_SamplingFeatureCollection.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 8.2.4.
- d) Test Type: Capability.

A.2.3 Spatial sampling feature interchange

The spatial sampling feature interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of a concrete subclass of SF_SpatialSamplingFeature.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 9.2.
- d) Test Type: Capability.

A.2.4 Sampling point interchange

The sampling point interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of SF_SamplingPoint.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 9.2.2.
- d) Test Type: Capability.

A.2.5 Sampling curve interchange

The sampling curve interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of SF_SamplingCurve.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 9.2.2.
- d) Test Type: Capability.

A.2.6 Sampling surface interchange

The sampling surface interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of SF_SamplingSurface.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 9.2.2.
- d) Test Type: Capability.

A.2.7 Sampling solid interchange

a) The sampling solid interchange test consists of the following:

- b) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of SF_SamplingSolid.
- c) Test Method: Inspect the documentation of the interchange schema.

d) Reference: ISO 19156, Clauses 9.2.2.

e) Test Type: Capability.

A.2.8 Specimen interchange

The specimen interchange test consists of the following:

- a) Test Purpose: Verify that an interchange schema correctly implements the mandatory attributes, associations and constraints of SF_Specimen.
- b) Test Method: Inspect the documentation of the interchange schema.
- c) Reference: ISO 19156, Clause 10.2.
- d) Test Type: Capability.

Annex B

(normative)

Utility classes

B.1 Introduction

The Observations and Measurements schema has dependencies on classes and packages from a number of other ISO 19100 series standards, as indicated in Clause 5.4, Figure 1 and Figure 8. A small number of classes are required which are not provided by existing external standards, but which are also not purely within scope for this standard. This Annex describes those classes.

B.2 Extensions to General Feature Model

B.2.1 GFI_Feature

The class GFI_Feature (Figure 14) is an instance of the «metaclass» GF_FeatureType (ISO 19109:2006). It represents the set of all classes which are feature types.

NOTE GFI_Feature is implemented in GML (ISO 19136:2007) by the element gml:AbstractFeature and type gml:AbstractFeatureType.

In an implementation this abstract class shall be substituted by a concrete class representing a feature type from an application schema associated with a domain of discourse (ISO 19109:2006, ISO/TS 19101:2002). Sampling Features (Clause 8) are a class of feature-types whose role is primarily associated with observations.

B.2.2 GFI_PropertyType

The class GFI_PropertyType (Figure 14) is an instance of the «metaclass» GF_PropertyType (ISO 19109:2006), representing feature properties.

An instance of GFI_PropertyType shall describe a property that is either assignable or observable (6.1.2), such as "temperature", "height", "colour", "material". A property-type may be an operation or function such as a spatio-temporal coverage. Property-type definitions may be organized into a hierarchy or ontology and managed in a register Error: Reference source not found and catalogued to support discovery functions.

EXAMPLE 'Ocean surface temperature' is a specialization of 'temperature', where the realm is restricted to the 'ocean', and the depth is some finite zone in proximity with the surface.

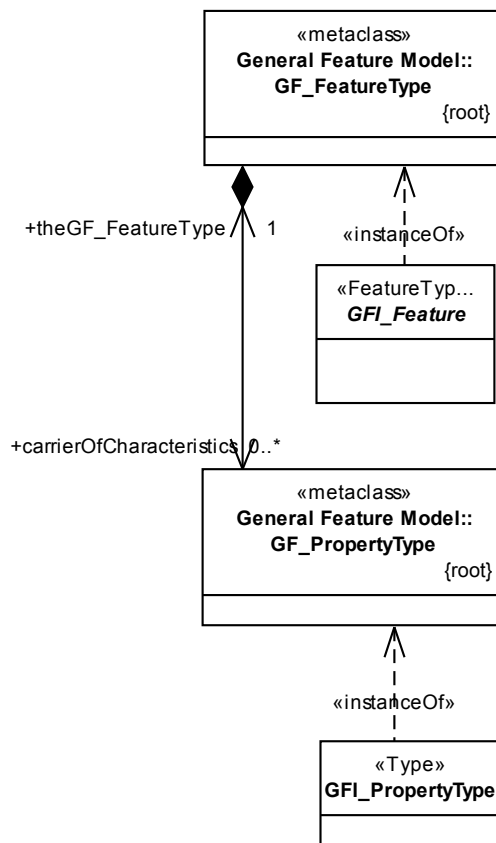

Figure 14—Feature Instance model

B.3 Extensions to Coverage schema

B.3.1 CVT_DiscreteTimeInstantCoverage

B.3.1.1 General

The class *CVT_DiscreteTimeInstantCoverage* (Figure 15) is a specialization of *CV_DiscreteCoverage* (ISO 19123:2005). *CVT_DiscreteTimeInstantCoverage* shall support one association.

B.3.1.2 CoverageFunction

The association *CoverageFunction* shall link the *CVT_DiscreteTimeInstantCoverage* to an ordered set of *CVT_TimeInstantValuePairs* that are the elements of the time series.

B.3.2 CVT_TimeInstantValuePair

B.3.2.1 General

The class *CVT_TimeInstantValuePair* (Figure 15) is a specialization of *CV_GeometryValuePair* (ISO 19123:2005). *CVT_TimeInstantValuePair* shall redefine one attribute inherited from *CV_GeometryValuePair*.

B.3.2.2 geometry

The attribute *geometry:TM_Instant* shall redefine the type of the *geometry* attribute inherited from *CV_GeometryValuePair*.

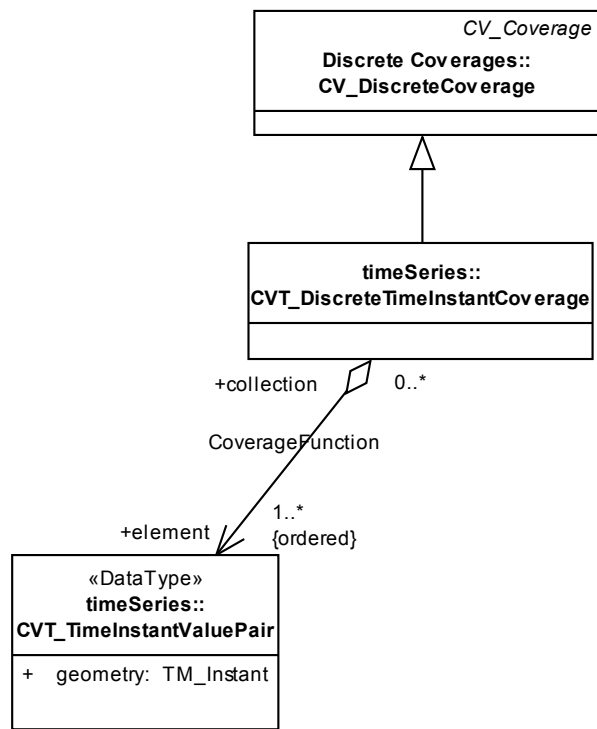

Figure 15 – Specialized coverage type for time-series

Mapping O&M terminology to common usage

C.1 Introduction

This International Standard defines terminology in support of a generic, cross-domain model for observations and measurements. Terms are taken from a variety of disciplines. The terms are used within the model in a consistent manner, but in order to achieve internal consistency, this varies from how the same terms are used in some application domains. In order to assist in the correct application of the model across domains, this Annex provides a mapping from O&M terminology to some domain vocabularies.

C.2 Mappings

C.2.1 Earth observations

Table 6: Earth Observations (EO)

O&M	EO	Example
Observation::result	observation value, measurement value, observation	35 ug/m ³
Observation::procedure	method, sensor	ASTER, U.S. EPA Federal Reference Method for PM _{2.5}
Observation::observedProperty	parameter, variable	Reflectance, Particulate Matter 2.5
Observation::featureOfInterest:SamplingSurface	2-D swath or scene	Sampling grid
SamplingSurface:sampledFeature	Earth surface	
Observation::featureOfInterest:SamplingSolid	3-D sampling space	Sampling grid
SamplingSolid::sampledFeature	media (air, water, ...), Global Change Master Directory "Topic"	troposphere

C.2.2 Earth science simulations

Table 7: Earth science simulations

O&M	Earth science
Observation::result	A model or field
Observation::observedProperty	Variable, parameter
Observation::featureofInterest:SamplingFeature	Section, swath, volume, grid
Observation::featureofInterest:SamplingFeature::sampledFeature (i.e. the ultimate or 'domain' feature of interest)	Atmosphere, ocean, solid earth
Observation::procedure	Earth process simulator
Observation::phenomenonTime	Future date (forecasts), past date (hindcasts)
Observation::resultTime	Simulator execution date
Observation::validTime	Period when result is intended to be used

C.2.3 Field observations in geology

Table 8: Geology field observations

O&M	Geology
Observation::featureOfInterest:SamplingFeatureCollection	Outcrop
SamplingFeatureCollection::relatedSamplingFeature:SamplingPoint	Location of structure observation
SamplingPoint::sampledFeature:GeologicUnit	Geologic Unit
Observation::phenomenonTime	Outcrop visit date
Observation::observedProperty	Strike and dip, lithology, alteration state, etc
SamplingFeatureCollection::relatedSamplingFeature:Specimen	Rock sample
Specimen::sampledFeature:GeologicUnit	Ore body, Geologic Unit

C.2.4 Earth observations

Table 9: Earth Observations (EO)

O&M	EO	Example
Observation::result	observation value, measurement value, observation	35 ug/m ³
Observation::procedure	method, sensor	ASTER, U.S. EPA Federal Reference Method for PM _{2.5}
Observation::observedProperty	parameter, variable	Reflectance, Particulate Matter 2.5
Observation::featureOfInterest:SamplingSurface	2-D swath or scene	Sampling grid
SamplingSurface:sampledFeature	Earth surface	
Observation::featureOfInterest:SamplingSolid	3-D sampling space	Sampling grid
SamplingSolid::sampledFeature	media (air, water, ...), Global Change Master Directory "Topic"	troposphere

C.2.5 Metrology

Table 10: Metrology

O&M	Metrology	Example: mass measurement
Observation::result	value	35 mg
Observation::procedure	instrument	balance
Observation::observedProperty	measurand	mass

C.2.6 Assay/Chemistry

Table 11: Assay/Chemistry

O&M	Geochemistry
Observation::featureOfInterest:Specimen	Sample
Specimen::sampledFeature:GeologicUnit	Ore body, Geologic Unit
Specimen::relatedSamplingFeature:Specimen	Pulp, separation
Specimen::materialClass	Whole-rock, mineral
Specimen::processingDetails	Sample preparation process
Specimen::samplingMethod	Sample collection process
Specimen::samplingLocation	Sample collection location
Specimen::size	Mass, length
Specimen::currentLocation	Store location
Specimen::samplingTime	Sample collection date
Observation::phenomenonTime	Sample collection date
Observation::resultTime	Analysis date
Observation::result	Analysis
Observation::observedProperty	Analyte
Observation::procedure	Instrument, analytical process

Best practices in use of the observation and sampling models

D.1 Features, coverages and observations – different views of information

ISO 19109:2006 describes the *feature* as a “fundamental unit of geographic information”. The “General Feature Model” (GFM) presented in ISO/TS 19101:2002 and 19109:2006 defines a feature type in terms of its characteristic set of properties, including attributes, association roles, and behaviours, as well as generalization and specialization relationships, and constraints.

Typical concrete feature types have names like “road”, “watercourse”, “mine”, “atmosphere”, etc. For a road the set of properties may include its name, its classification, the curve describing its centreline, the number of lanes, the surface material, etc. The complete description of a road instance, therefore, is the set of values for the set of properties that define a road type. This use of the feature model is object-centric, and supports a viewpoint of the world in terms of the set of discrete identifiable objects that occupy it.

The principle alternative model for geographic information is the *coverage*, described in ISO 19123:2005. This viewpoint focuses on the variation of a property within the (spatio-temporal) domain of interest. The domain may be a scene, a grid, a transportation network, a volume, a set of sampling stations, etc. The range of the coverage may be any property, such as reflectance, material-type, concentration of some pollutant, number of lanes etc. But the key to the coverage viewpoint is that it is property-centric, concerning the distribution of the values of a property within its domain space.

These viewpoints are not exclusive, and both are used in analysis and modelling. For example, a feature may be detected from analysis of variation of a property in a region of interest (e.g. an ore-body from a distribution of assay values). And for some feature types, the value of one or more properties may vary across the feature, in which case the shape of the feature provides the coverage domain (e.g. ore-grade within a mine).

Observations focus on the data collection event. An act of Observation serves to assign a value to a property of a feature. If the property is non-constant, the value may be a function or coverage. The results of a set of observations of different properties on the same feature of interest may provide a complete description of the feature instance. Alternatively, the results of a set of observations of the same property on a set of different features provide a discrete coverage of that property over a domain composed of the geometry of the feature set. The other properties of the Observation are metadata concerning the estimation of the value(s) of a property on a feature of interest.

In particular, Observations concern properties (e.g. shape, colour) whose values are determined using an identifiable procedure, in which there is a finite uncertainty in the result. This may be contrasted with properties whose values are specified by assertion (e.g. name, owner) and are therefore exact. The observation instance provides “metadata” for the property value-estimation process.

An observation event is clearly a “feature” in its own right, according to the GFM definition. An observation instance is a useful unit of information, therefore observation is a feature type.

Transformation between viewpoints is frequently required. Some of the observation specializations provide an explicit demonstration of the transformation.

This is illustrated in Figure 14, which schematically shows a dataset comprising values of a set of properties at a set of locations. A row of the table provides the complete description of the properties at a single location. This is a representation of a potential feature description. A column of the table describes the variation of a single property across the set of locations. This is a representation of a discrete coverage. A single cell in the table provides the value of a single property on a single feature. This may be the result of an observation.

Observations, Coverage and Feature representations may be associated with different phases of the data-processing cycle or value-chain:

- The observation view is associated with data collection, when an observation event causes values for a property of a feature to be determined, and during data entry when the data-store is updated by inserting values into fields in the datastore;
- A coverage view may be assembled from results of observations of a specific property, and represents data assembled for analysis, when the objective is to find signals in the variation of a property over a domain;
- A discrete feature description is a “summary” viewpoint, assembled from results of observation on the same target, or an “inferred” viewpoint, by extraction of a signal from a coverage.

Location	Properties			
	Property 1	Property 2	...	Property m
(x_1, y_1)	Value ₁ ¹	Value ₁ ²	...	Value ₁ ^m
(x_2, y_2)	Value ₂ ¹	Value ₂ ²	...	Value ₂ ^m
(x_3, y_3)	Value ₃ ¹	Value ₃ ²	...	Value ₃ ^m
Feature 3				
(x_n, y_n)	Value _n ¹	Value _n ²	...	Value _n ^m

Coverage 2

Figure 14 - Tabular representation of information associated with a set of locations.

D.2 Observation concerns

D.2.1 Domain specialization

Specialization of the observation model for an application domain is accomplished primarily using a domain application schema and its feature-type catalogue. For example, an instance of a feature-type in the domain feature-type catalogue will provide the ultimate feature of interest for the investigation of which the observation is a part, and the characteristic properties of the feature-type provide potential observed properties. A description of a sensor or process familiar within the application domain is the value of the observation procedure.

The observation model encourages encapsulation of domain specialization in the associated classes, and the observation class itself rarely needs specialization.

Nevertheless, other choices could be made in partitioning information between the classes in the model. For some applications it may be convenient for information that is strictly associated with a second-layer object (procedure, feature of interest) to be associated with a specialized observation type.

For example, when measuring chemistry or contamination, the process often involves retrieving *specimens* from a sampling station, which are then sent to a laboratory for analysis. The specimen is a very tangible feature instance, with identity. For some applications it may be important to recognize the existence of the specimen, and retain a separate description of it. However, in other applications, particularly when the focus is on monitoring the change in a property at a sampling station, the existence of a series of distinct specimens is of minor or no interest. In this case creating a series of objects and identifiers is superfluous to the user's requirements.

Nevertheless, some properties that might be strictly associated with such a specimen must still be recorded, such as “sampling elevation” in a water or atmospheric column. A number of choices may be made. For example, the elevation could be

- (a) a property of each distinct specimen on which atomic observations are actually made,
- (b) a property of the sampling station (which would require distinct stations for all elevations at which observations are made),
- (c) a parameter of the observation procedure, (which makes the procedure specific to this observation series only) or
- (d) a parameter of the observation event, either using the soft-typed `procedureParameter`, or through specialization of the observation type.

Any of these is a legitimate approach. The optimum one will be dependent on the application.

All of the classes in the models presented here for observations and procedures may be further specialized for domain-specific purposes. Additional attributes and associations may be added as necessary.

EXAMPLE “Assay” may be derived from `Measurement`, fixing the `observedProperty` to be “`ChemicalConcentration`” and adding an additional attribute “`analyte`”.

D.2.2 Comparison with provider-oriented models

The O&M model is intended to provide a basic output- or user-oriented information model for sensor web and related applications. The goal is to provide a common language for discourse regarding sensor and observation systems.

In comparison, TML D.3.5 and SensorML D.3.5 have process- or provider-oriented data models. These are usually used to describe data at an early stage in the data processing and value-adding chain. This may be prior to the details of the feature-of-interest and observed property being assembled and assigned to the result in a way that carries the key semantics to end-users of observation data. In particular, part of a TML or SensorML datastream may include information that must be processed to determine the position of the target or feature-of-interest. At the early processing stage such positional and timing information may be embedded within the result.

Nevertheless, even within these low-level models the O&M formalization may be applied. The proximate feature-of-interest is the vicinity of the sensor. The observed property is a composite type including components representing observation timing, and position and attitude of a sensor, etc. This must be processed to obtain the details of the ultimate feature of interest. The procedure is a sensor package including elements that capture all of the elements of the composite phenomenon or property-type, etc.

D.2.3 Observation discovery and use

The Observation and Measurements model presented here offers a user-oriented viewpoint. The information object is characterized by a small set of properties, which are likely to be of interest to a user for discovery and request of observation data. The user will typically be interested primarily in a feature of interest, or the variation of a phenomenon. The model provides these items as first order elements. An interface to observation information should expose these properties explicitly.

SOS D.3.5 leverages the O&M model directly, with *featureOfInterest* and *observedProperty* being (1) explicit classifiers for an `observationOffering` in the capabilities description, used for discovery, and (2) explicit parameters in the `GetObservation` request. From a user point of view, the sensor or procedure description is primarily *metadata*, which is only of interest to specialists during discovery, and then to assist evaluation or processing of individual results.

Each of these associated objects (sensor or procedure, target feature, phenomenon) may require a complex description. Hence they are modelled as distinct classes, which may be as simple or complex as necessary. In the XML serialized representation following the GML pattern, they may appear inline, perhaps described using one of the models presented here, or they may be indicated by reference using a URI. The URI identifier may be a URL link or service call, which should resolve immediately to yield a complete resource. Or it may be a

canonical identifier, such as a URN, which the user and provider are preconfigured to recognise and understand.

On the other hand, TML and SensorML take a process- or provider-oriented viewpoint. Discovery and request is based primarily on the user having knowledge of specific sensor systems and their application. While this is a reasonable assumption within technical communities, specialist knowledge of sensor systems would not be routinely available within a broader set of potential users of sensor data, particularly as this is made widely available through interfaces like SOS.

D.2.4 Observations vs. Interpretations

Some conceptual frameworks make a fundamental distinction between *observations* and *interpretations* as the basis for their information modelling approach. This supports a pattern in which observations are given precedence and archived, while interpretations are more transient, being the result of applying the current algorithms and paradigms to the currently available observations.

An alternative view is that the distinction is not absolute, but is one of degree. Even the most trivial "observations" are mediated by some theory or procedure. For example, the primary measurement when using a mercury-in-glass thermometer is the position of the meniscus relative to graduations. This allows the length of the column to be estimated. A theory of thermal expansion plus a calibration for the physical realization of the instrument allows conversion to an inferred temperature. Other observations and measurements all involve some kind of processing from the primary observable. For modern instruments the primary observable is almost always voltage or resistance or frequency from some kind of sensing element, so the "procedure" typically involves calibrations, etc, built on a theory of operation for the sensor. But the same high-level information model - that every "value" is an estimate of the value of a property, generated using a procedure and inputs - applies to both "observations" and "interpretations". It is just that the higher the semantic value of the estimate, the more theory and processing is involved.

In some cases it may be useful to explicitly describe the processing chain instance that has taken a more primitive observations (e.g. an image) and retrieved a higher level observation (e.g. the presence of a certain type of feature instance) through the application of one or more processing steps.

D.3 Sampling concerns

D.3.1 Sampling feature acts as observation-collector

The sampling feature model satisfies the requirements described in Clause 8.1. Sampling features provide

- (i) an intermediate feature-type that allows the assignment of primitive and intermediate properties within a processing chain;
- (ii) a context for the description of sampling regimes.

In addition, sampling features provide a feature-type for observation collections, which have the homogeneity constraint that they share a common feature-of-interest. This provides an access route to observation information that is convenient under some project scenarios, where the sampling strategy provides the logical organization of observations.

Examples: an observational mission or campaign may organize its data according to flightlines, ship's tracks, outcrops, sampling-stations, quadrats, etc, or an observation archive or museum may organize observations by specimen.

D.3.2 Observation feature of interest

Application of the Observations and Measurements model requires careful attention to identify the feature of interest correctly. This may be straightforward if the observation is clearly concerned with an easily identified concrete feature type from a domain model. However, the ultimate feature of interest to the investigator may not be the proximate feature of interest for the observation. In some cases a careful analysis reveals that the type of the feature of interest had not previously been identified in the application domain.

The key is that the proximate feature of interest must be capable of carrying this result as the value or component of the value of a relevant property. So a useful approach in analysis is to consider what the *result* of the observation is, and then the feature of interest may be deduced since it must have a property with this result as its value. If an observation produces a result with several elements, or if there are a series of related observations with different results, then this may help further refine the understanding the type of the true feature of interest.

Example: In monitoring situations, the feature of interest is often a typed event or “occurrence”. The observation procedure(s) provides an estimate of (i) time, (ii) location, and (iii) type (e.g. species, identity) of the party involved.

D.3.3 Processing chains and intermediate features of interest

The Observation model implies a direct relationship between the observed property and the type of the feature of interest (e.g. a specimen type has a property ‘mass’ & observation observed property is ‘mass’). However, as discussed in sub-clause 8.1.1.2 the relationship between the observed property and property(ies) of the ultimate feature-of-interest is often more complex.

The Sampling Feature model is a mechanism for preserving the strict association, by providing an specific intermediate feature-type whose observable properties are unspecified in advance, but supplied through an unlimited set of related observations. The path from a sensed property obtained through observations related to the sampling feature, to the interesting property on the ultimate feature-of-interest, is modelled as a processing chain.

If intermediate values are explicit, then the processing chain may be modelled as a sequence of “observations”, with intermediate features of interest carrying intermediate property-types. Each intermediate value must apply to a feature-of-interest that bears this property, or a sampling feature. Note that the types of these features may not be conventional or immediately recognisable, but the coherence of the Observations and Measurements model does imply their existence. Hence, if any intermediate result is made explicit, then a suitable intermediate feature must also be identified.

D.3.4 Variable properties and sub-sampling

The shape of an extensive sampling feature defines a manifold within which a varying property may be characterized, and hence within which subsampling may be undertaken. The shape provides a complete sampling domain, but does not specify any particular decomposition. Sub-sampling may be described through identified related sampling features, or as domain elements of a discrete coverage representation of the variation of a property within the sampling feature. The shape of the sampling feature is the context for domain decomposition.

Example: Logs of different properties along a well or borehole may use different intervals, and sub-samples may be either spatially instantaneous, or averaged in some way over an interval. The position of the samples may be conveniently described in terms of offsets in a linear coordinate reference system that is defined by the shape of the well axis.

Time dependent properties may be observed if a sampling feature is temporally-persistent. .

Example: The temperature of the atmosphere at a weather station varies as a function of time.

Properties observed using a sampling feature may depend on non-spatio-temporal axes.

Example: The density of a specimen varies as a function of temperature.

The specialization of sampling features follows common practice in focussing on conventional spatial dimensions. Properties observed on sampling features may be time-dependent, but the temporal axis does not generally contribute to the classification of sampling feature classes. Sampling feature identity is usually less time-dependent than property value.

D.3.5 Consistency constraints for sampling coverage observations

An important class of observations are those made by sampling a property of a temporally-persistent extensive feature, where the observation result is a discrete coverage over the sampling domain. Special cases include the OM_DiscreteCoverageObservation subclasses, but more generally the sampling geometry may be a compound structure in time and space.

Example: Physical oceanographers deploy expendable bathythermographs to measure seawater temperature as a discrete coverage along the sampling curve traced by the instrument's descent (regarded as instantaneous with respect to ocean dynamics).

Example: Meteorologists use radar wind profilers to measure wind speed and direction as time-series' of discrete coverages at fixed heights on a sampling curve extending vertically from the Earth's surface.

Example Mobile sensors are used experimentally for monitoring urban air quality, by measuring concentration of ambient pollutants as a coverage over the sensor's spatio-temporal trajectory along a sampling curve.

In many of these applications there are consistency constraints that relate the observation, a sampling feature and a coverage result (Figure 16), which could be expressed formally (at least in part) as OCL constraints D.3.5 on a specialized Observation class called 'SamplingCoverageObservation':

- the feature of interest of the sampling coverage observation is a sampling feature:
 - self.ocIsKindOf(SamplingCoverageObservation) and
featureOfInterest.ocIsKindOf(SF_SpatialSamplingFeature)
- the observed property shall be consistent with the range type of the coverage result:
 - observedProperty.memberName = result.rangeType.name
- the shape of the sampling feature of interest shall contain the spatial elements of the domain of the coverage result:
 - result.domainElement->forAll(d : CV_DomainObject | featureOfInterest.shape::contains(d.spatialElement))
- the phenomenon time of the observation shall correspond to the temporal extent of the domain of the coverage result:
 - result.domainElement->forAll(d : CV_DomainObject | phenomenonTime::relativePosition(d.temporalElement) = TM_RelativePosition.Contains)

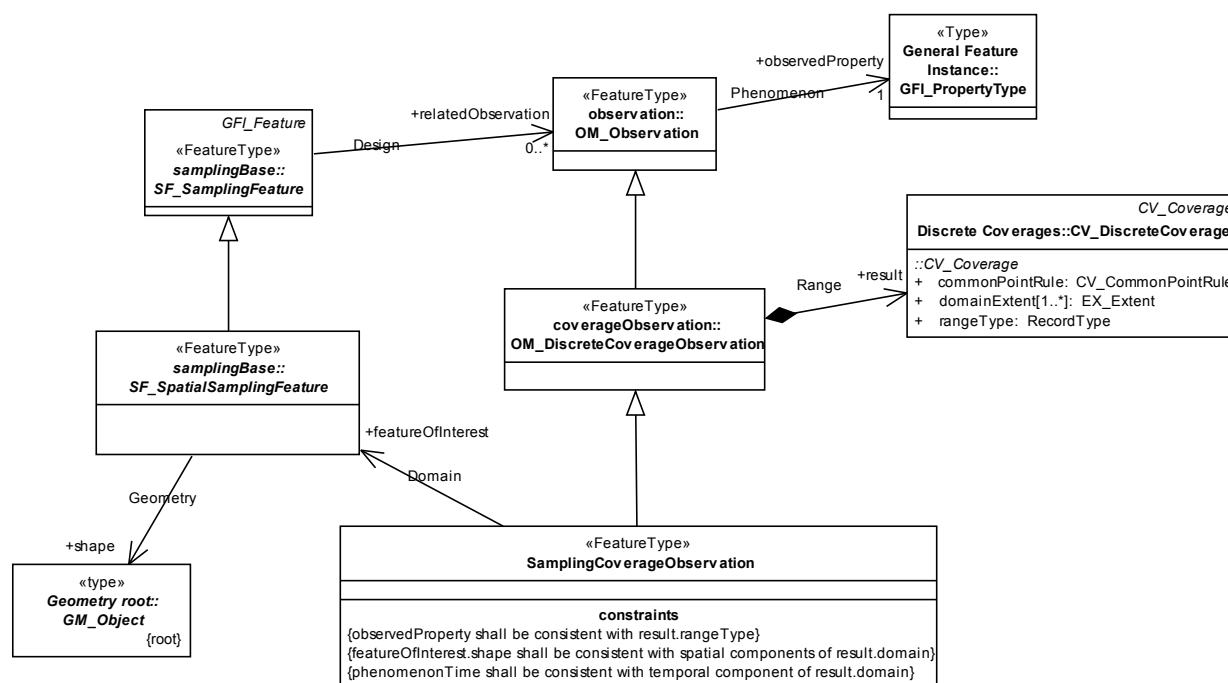

Figure 16 – Consistency constraints for sampling coverage observations

NOTE Many such observation results may be accommodated by using appropriate application of a CV_DiscreteGridPointCoverage result, as shown in Table 12.

Table 12 – Examples of coverage results for different sampling regimes

Observation class	Example	Spatial sampling feature	Coverage result
Profile	Expendable bathythermograph observation of seawater temperature	SF_SamplingCurve	<ul style="list-style-type: none"> one-dimensional grid at fixed (x,y,t) within four-dimensional (x-y-z-t) CRS grid axis aligned with CRS z-axis
ProfileTimeSeries	Radar wind profiler measurement	SF_SamplingCurve	<ul style="list-style-type: none"> two-dimensional grid at fixed (x,y) within four-dimensional (x,y,z,t) CRS grid axes aligned with CRS z- and t-axes
Trajectory	Pollutant concentration from mobile air quality sensor	SF_SamplingCurve	<ul style="list-style-type: none"> one-dimensional grid within four-dimensional (x-y-z-t) CRS
Section	Vertical profiles of water current measurements taken by an acoustic doppler current profiler towed along a ship's track	SF_SamplingSurface	<ul style="list-style-type: none"> two-dimensional grid within four-dimensional (x-y-z-t) CRS one grid axis aligned with CRS z-axis
